FUNCTIONAL DESCRIPTION

The device has a common diagnostic output for both channels which indicates open load in on-state, open load in off-state, over temperature conditions and stuck-on to V_{CC} .

From the falling edge of the input signal, the status output, initially low to signal a fault condition (overtemperature or open load on-state), will go back to a high state with a different delay in case of overtemperature (t_{povl}) and in case of open load (t_{pol}) respectively. This feature allows to discriminate the nature of the detected fault. To protect the device against short circuit and over current condition, the thermal protection turns the integrated Power MOS off at a minimum junction temperature of 140°C . When this temperature returns to 125°C the switch is automatically turned on again. In short circuit the protection reacts with virtually no delay, the sensor (one for each channel) being located inside each of the two Power MOS areas. This positioning allows the device to operate with one channel in automatic thermal cycling and the other one on a normal load. An internal function of the devices ensures the fast demagnetization of inductive loads with a typical voltage (V_{demag}) of -18V . This function allows to greatly reduce the power dissipation according to the formula:

$$P_{\text{dem}} = 0.5 \cdot L_{\text{load}} \cdot (I_{\text{load}})^2 \cdot [(V_{\text{CC}} + V_{\text{demag}}) / V_{\text{demag}}] \cdot f$$

where f = switching frequency and

V_{demag} = demagnetization voltage

The maximum inductance which causes the chip temperature to reach the shut-down temperature in a specified thermal environment is a function of the load current for a fixed V_{CC} , V_{demag} and f according to the above formula. In this device if the GND pin is disconnected, with V_{CC} not exceeding 16V , both channel will switch off.

PROTECTING THE DEVICE AGAINST REVERSE BATTERY

The simplest way to protect the device against a continuous reverse battery voltage (-26V) is to insert a Schottky diode between pin 1 (GND) and ground, as shown in the typical application circuit (Figure 9).

The consequences of the voltage drop across this diode are as follows:

- If the input is pulled to power GND, a negative voltage of $-V_f$ is seen by the device. (V_{IL} , V_{IH} thresholds and V_{STAT} are increased by V_f with respect to power GND).
- The undervoltage shutdown level is increased by V_f .

If there is no need for the control unit to handle external analog signals referred to the power GND, the best approach is to connect the reference potential of the control unit to node [1] (see application circuit in Figure 10), which becomes the common signal GND for the whole control board avoiding shift of V_{IH} , V_{IL} and V_{STAT} . This solution allows the use of a standard diode.

Table 9. Truth Table

		Input 1	Input 2	Output 1	Output 2	Diagnostic
Normal Operation		L	L	L	L	H
		H	H	H	H	H
		L	H	L	H	H
		H	L	H	L	H
Under voltage		X	X	L	L	H
Thermal Shutdown	Channel 1	H	X	L	X	L
	Channel 2	X	H	X	L	L
Open Load	Channel 1	H	X	H	X	L
		L	L	L	L	L ⁽⁷⁾
	Channel 2	X	H	X	H	L
		L	L	L	L	L ⁽⁷⁾
Output Shorted to V _{CC}	Channel 1	H	X	H	X	L
		L	L	H	L	L
	Channel 2	X	H	X	H	L
		L	L	L	H	L

Note: 7. With additional external resistor.
