

# CAT37

## CMOS White LED Driver Boost Converter

### Description

The CAT37 is a DC/DC step up converter that delivers a regulated output current. Operation at a constant switching frequency of 1.2 MHz allows the device to be used with very small value external inductor and ceramic capacitors.

The CAT37 is targeted to drive multiple white light-emitting diodes (LEDs) connected in series and provides the necessary regulated current to control the brightness and the color purity. An external resistor R1 controls the output current level. LED currents of up to 40 mA can be supported over a wide range of input supply voltages from 2.5 V to 7 V, making the device ideal for battery-powered applications.

A high voltage output stage allows up to 4 White LEDs to be driven in series. Series drive provides inherent current matching.

LED dimming can be done by using a DC voltage, a logic signal, or a pulse width modulation (PWM) signal. The shutdown input pin allows the device to be placed in power-down mode with “near zero” quiescent current.

In addition to overcurrent limiting protection, the device also includes detection circuitry to ensure protection against open-circuit load fault conditions.

The device is available in a low profile (1 mm max height) 5-lead TSOT-23 package.

### Features

- Low Quiescent Ground Current (0.5 mA Typical)
- Power Efficiency Over 80%
- Compatible Pinout with LT1937
- Adjustable Output Current (up to 40 mA)
- High Frequency 1.2 MHz Operation
- Input Voltage Operation down to 2.5 V
- Low Resistance (0.5  $\Omega$ ) Power Switch
- Drives up to 4 White LEDs in Series
- Shutdown Current Less than 1  $\mu$ A
- Load Fault Protection Against Open-circuits
- Low Value External Components
- Low Profile (1 mm) TSOT-23 5-lead Package
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

### Applications

- Color LCD and Keypad Backlighting
- Cellular Phones
- Handheld Terminals
- Digital Cameras
- PDAs/Games
- Portable MP3 Players

## Typical Application Circuit

Figure 1. Driver for Four High-Brightness White LEDs

Table 1. PIN DESCRIPTION

Pin Number	Name	Function
1	SW	Switch pin. This is the drain of the internal power switch. For minimum EMI, minimize the trace area connected to this pin.
2	GND	Ground pin. Connect pin 2 to ground.
3	FB	LED (cathode) connection pin.
4	$\overline{\text{SHDN}}$	Shutdown pin.
5	VIN	Input supply pin. This pin should be bypassed with a capacitor to ground. A 1 $\mu\text{F}$ capacitor mounted close to the pin is recommended.

Table 2. ABSOLUTE MAXIMUM RATINGS

Parameter	Rating	Unit
$V_{\text{IN}}$ , FB, $\overline{\text{SHDN}}$ voltage	8	V
SW voltage	20	V
Storage Temperature Range	-65 to +160	°C
Junction Temperature	125	°C
Lead Soldering Temperature (10 secs)	300	°C
ESD Rating – Human Body Model	2000	V

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

Table 3. RECOMMENDED OPERATING CONDITIONS

Parameter	Range	Unit
$V_{\text{IN}}$	2.5 to 7	V
Ambient Temperature Range	-40 to +85	°C
Inductor L1	$6.8 \pm 20\%$ typical	$\mu\text{H}$
Input Capacitor C1	$1.0 \pm 20\%$ typical	$\mu\text{F}$
Output Capacitor C2	$1.0 \pm 20\%$ typical	$\mu\text{F}$
$I_{\text{LED}}$ with 1 to 4 LEDs in series	0 to 20	mA

NOTE: Typical application circuit with external components is shown above.

## CAT37

### Operation

The CAT37 device is a high efficiency, constant frequency, current regulating boost driver for white LEDs.

The device includes a switch and an internally compensated loop for the regulation of the current in the LEDs.

Operation can be best understood by examining the block diagram. The FB pin is regulated at 95 mV and the current through the external resistor will set the regulated current in the LEDs at:

$$I_{LED} = \frac{0.095}{R1}$$

### Block Diagram

Figure 13. CAT37 Block Diagram

While maintaining LED current regulation, the CAT37 boost converter automatically adjusts the FB pin voltage to be as low as possible. A low FB pin voltage ensures high efficiency.

Current through the internal power switch is continuously monitored cycle-by-cycle. If the current limit is exceeded, the switch is immediately turned off, protecting the device, for the remainder of the cycle.

PWM dimming operation can be achieved by switching the  $\overline{\text{SHDN}}$  pin or by pulling the FB pin higher than 95 mV.

## Application Information

### Capacitor Selection

Low ESR (equivalent series resistance) capacitors should be used at the output to minimize the output ripple voltage. The low ESR and small package options available with multilayer ceramic capacitors make them excellent choices. The X5R and X7R capacitor types are preferred because they retain their capacitance over wider voltage and temperature ranges than the Y5V or Z5U types. A 1.0  $\mu\text{F}$  output capacitor is recommended for most applications.

The voltage rating of the output capacitor C2 depends on the number of LEDs driven in the series. A 16 V ceramic capacitor is recommended when driving 3 or 4 LEDs.

Low profile ceramic capacitors with a 1 mm maximum height/thickness are available for designs height requirements. Ceramic capacitors also make a good choice for the input capacitor, which should be mounted as close as possible to the CAT37. A 1  $\mu\text{F}$  or 4.7  $\mu\text{F}$  input capacitor is recommended. Table 5 shows a list of several ceramic capacitor manufacturers. Consult the manufacturers for detailed information as new products and package options are introduced regularly.

Kemet	<a href="http://www.kemet.com">www.kemet.com</a>
AVX	<a href="http://www.avxcorp.com">www.avxcorp.com</a>

### Diode Selection

Schottky diodes, with their low forward voltage drop and fast switching speed, are the ideal choice for high efficiency applications. Table 6 shows several different Schottky diodes that work well with the CAT37. Make sure that the diode has a voltage rating greater than the output voltage. The diode conducts current only when the power switch is turned off (typically less than one-third the time), so a 0.4 A or 0.5 A diode will be sufficient for most designs.

MBR0540	

### LED Current Programming

The LED current is programmed with a single resistor connected to the FB pin. The FB pin is internally regulated to 95 mV, which sets the current flowing through R1 and the LEDs as equal to  $0.095/R1$ . For the best accuracy, a 1% or better resistor is recommended. Table 7 shows several typical 1% R1 values.

**Table 7. R1 RESISTOR VALUES**

$I_{LED}$ (mA)	R1 ( $\Omega$ )
40	2.37
30	3.16
20	4.75
15	6.34
12	7.87
10	9.53
5	19.1

For other LED current values, use the following equation to choose R1.

$$R1 = \frac{0.095}{I_{LED}}$$

Most white LEDs are driven at maximum currents of 15 mA to 20 mA. Some higher power designs will use two parallel strings of LEDs for greater light output, resulting in 30 mA to 40 mA (two strings of 15 mA to 20 mA) flowing through the R1 resistor.

### LED Dimming with DC Signal

Dimming the LEDs can be done by applying a variable DC voltage as shown on Figure 14. As the  $V_{DC}$  increase the voltage across R1 decreases and therefore lower the LED current. The resistors R2 and R3 must be large enough so that their current (tens of  $\mu A$ ) is much smaller than the LED current but much larger than the FB leakage current ( $I_{FB}$ ). When adjusting  $V_{DC}$  between 0 V and 2 V, the resistors shown on Figure 14 will set the LED current between 0 mA and 15 mA.

### LED Dimming with PWM Signal

PWM brightness control provides the widest dimming range (greater than 20:1). By turning the LEDs ON and OFF using the control signal, the LEDs operate at either zero or full current, but their average current changes with the PWM signal duty cycle. Typically, a 5 kHz to 40 kHz PWM signal is used.

A filtered PWM signal is used to dim the LEDs, as shown in Figure 15.

In addition to providing the widest dimming range, PWM brightness control also ensures the “purest” white LED color over the entire dimming range. The true color of a white LED changes with operating current, and is the “purest” white at a specific forward current, usually 15 mA or 20 mA. If the LED current is less than or more than this value, the emitted light becomes more blue. Applications involving color LCDs can find the blue tint objectionable.

Figure 14. Dimming with a DC Voltage

Figure 15. Dimming with a Filtered PWM Signal

Figure 16. Dimming with a Logic Signal

### LED Dimming with a Logic Signal

For applications that need to adjust the LED brightness in discrete steps, a logic signal can be used as shown in Figure 16. R1 sets the minimum LED current value (when the NMOS switch is OFF):

$$R1 = \frac{0.095 \text{ V}}{I_{LED(MIN)}}$$

$R_{INCR}$  determines how much LED current increases when the external NMOS switch is turned ON.

$$R_{INCR} = \frac{0.095 \text{ V}}{I_{LED(INCREASE)}}$$

### PCB Layout Guidelines

The CAT37 is a high-frequency switching regulator where proper PCB board layout and component placement can minimize noise and radiation and increase efficiency. To maximize efficiency, the CAT37 design has fast switch rise and fall times. To prevent radiation and high frequency resonance problems minimize the length and area of all traces connected to the SW pin and use a ground plane under the switching regulator.

The SW pin, schottky diode and capacitor C2 signal path should be kept as short as possible. The ground connection for the R1 resistor should be tied directly to the GND pin and not be shared with other components.
