Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All currents into pins are positive; all voltages are referenced to GND unless otherwise specified.

Note 3: Pulsed less than 5μs.

Note 4: The connection circuitry always regulates the output to a higher

voltage than its input. The magnitude of this offset voltage as a function of the pull-up resistor and V_{CC} voltage is shown in the Typical Performance Characteristics section.

Note 5: $I_{PULLUPAC}$ varies with temperature and V_{CC} voltage, as shown in the Typical Performance Characteristics section.

Note 6: Determined by design, not tested in production.

Note 7: I_{CC} test performed with connection circuitry active.

Note 8: When floating, the $\overline{ACC}$ pin can tolerate ±5μA of leakage.

TYPICAL PERFORMANCE CHARACTERISTICS $T_A = 25^{\circ}\text{C}$ unless otherwise indicated.

PIN FUNCTIONS

ENABLE (Pin 1): Connection Enable. This is a digital threshold input pin. For normal operation ENABLE is high. Driving ENABLE below 0.8V isolates SDAIN from SDAOUT, SCLIN from SCLOUT, asserts READY low and disables automatic clocking. A rising edge on ENABLE after a fault has occurred unconditionally forces a connection between SDAIN, SDAOUT and SCLIN, SCLOUT.

SCLOUT (Pin 2): Serial Clock Output. Connect this pin to the SCL bus on the card.

SCLIN (Pin 3): Serial Clock Input. Connect this pin to SCL on the bus backplane.

ACC (Pin 4): Rise-Time Accelerator Control. Connect $\overline{\text{ACC}}$ to V_{CC} to disable all four accelerators. Connect $\overline{\text{ACC}}$ to GND to enable all four accelerators. Float $\overline{\text{ACC}}$ to enable the SDAOUT and SCLOUT accelerators only. For applications when V_{CC} is greater than the bus pull-up voltage, connect $\overline{\text{ACC}}$ to V_{CC} .

GND (Pin 5): Device Ground. Connect this pin to a ground plane for best results.

READY (Pin 6): Connection Status Flag. READY provides a digital flag which indicates the status of the connection circuitry described in the “Connection Circuitry” section. Connect a resistor of 10k to V_{CC} to provide the pull-up.

FAULT (Pin 7): Bus Stuck Low Fault. $\overline{\text{FAULT}}$ is an open drain N-channel MOSFET which pulls low to signal a bus stuck low condition. In normal operation, $\overline{\text{FAULT}}$ is high. Connect a 10k resistor from this pin to V_{CC} to provide the pull-up.

SDAIN (Pin 8): Serial Data Input. Connect this pin to the SDA bus on the backplane.

SDAOUT (Pin 9): Serial Data Output. Connect this pin to the SDA bus on the card.

V_{CC} (Pin 10): Supply Voltage Input. Place a bypass capacitor of at least 0.01 μ F close to V_{CC} for best results.

Exposed Pad (Pin 11, DFN Only): Exposed pad may be left open or connected to the ground plane.

BLOCK DIAGRAM

LTC4304 2-Wire Bus Buffer with Stuck Bus Protection

OPERATION

Start-Up

When the LTC4304 first receives power on its V_{CC} pin, either during power up or live insertion, it starts in an under voltage lockout (UVLO) state, ignoring any activity on the SDA or SCL pins until V_{CC} rises above 2.5V (typical).

During this time, the precharge circuitry is active and forces 1V through 200K nominal resistors to the SDA and SCL pins. Because the I/O card is being plugged into a live backplane, the voltage on the backplane SDA and SCL busses may be anywhere between 0V and V_{CC} . Precharging the SCL and SDA pins to 1V minimizes the worst-case voltage differential these pins will see at the moment of connection, therefore minimizing the amount of disturbance caused by the I/O card.

Once the LTC4304 comes out of UVLO, it assumes that SDAIN and SCLIN have been inserted into a live system and that SDAOUT and SCLOUT are being powered up at the same time as itself. Therefore, it looks for either a stop bit or bus idle condition on the input side to indicate the completion of a data transaction. When either one occurs, the part also verifies that both the SDAOUT and SCLOUT voltages are high. When all of these conditions are met, the input-to-output connection circuitry is activated, joining the SDA and SCL busses on the I/O card with those on the backplane and READY goes high.

Connection Circuitry

Once the connection circuitry is activated, the functionality of the SDAIN and SDAOUT pins is identical. A low forced on either pin at any time results in both pin voltages being low. **For proper operation, logic low input voltages should be no higher than 0.4V with respect to the ground pin voltage of the LTC4304.** SDAIN and SDAOUT enter a logic high state only when all devices on both SDAIN and SDAOUT release high. The same is true for SCLIN and SCLOUT. This important feature ensures that clock stretching, clock synchronization, arbitration and the acknowledge protocol always work, regardless of how the devices in the system are tied to the LTC4304.

Another key feature of the connection circuitry is that it provides bidirectional buffering, keeping the backplane and card capacitances isolated. Because of this isolation,

the waveforms on the backplane busses look slightly different than the corresponding card bus waveforms, as described here.

Input to Output Offset Voltage

When a logic low voltage, V_{LOW1} , is driven on any of the LTC4304's data or clock pins, the LTC4304 regulates the voltage on the opposite side of the part (call it V_{LOW2}) to a slightly higher voltage, as directed by the following equation:

$$V_{LOW2} = V_{LOW1} + 75\text{mV} + (V_{CC}/R) \cdot 20\Omega \text{ (typical)}$$

where R is the bus pull-up resistance in ohms. For example, if a device is forcing SDAOUT to 10mV where $V_{CC} = 3.3\text{V}$ and the pull-up resistor R on SDAIN is 10k, then the voltage on SDAIN = $10\text{mV} + 75\text{mV} + (3.3/10000) \cdot 20 = 91.6\text{mV}$ (typical). See the Typical Performance Characteristics section for curves showing the offset voltage as a function of V_{CC} and R.

Bus Stuck Low Timeout

When SDAOUT or SCLOUT is low, an internal timer starts. The timer is only reset when SDAOUT and SCLOUT are both high. If they do not go high within 30ms (typical), FAULT pulls low indicating a bus stuck condition and the connection between SDAIN and SDAOUT, and SCLIN and SCLOUT is broken. After a delay of at least 40 μ s, the LTC4304 automatically generates up to 16 clock pulses at 8.5kHz (typical) on SCLOUT in an attempt to unstick the bus. When SDAOUT and SCLOUT go high, FAULT is cleared and reconnection occurs when the conditions described in the "Start-Up" section above are satisfied.

When powering up into a bus stuck low condition, the connection circuitry joining the SDA and SCL busses on the I/O card with those on the backplane is not activated. 30ms after UVLO, FAULT pulls low indicating a bus stuck low condition, and automatic clocking takes place as described above.

Propagation Delays

During a rising edge, the rise-time on each side is determined by the bus pull-up resistor and the equivalent capacitance on the line. If the pull-up resistors are the

OPERATION

Figure 1. Input-Output Connection t_{PLH}

same, a difference in rise-time occurs which is directly proportional to the difference in capacitance between the two sides. This effect is displayed in Figure 1 for a $V_{CC} = 3.3V$ and a 10k pull-up resistor on each side (50pF on one side and 150pF on the other). Since the output side has less capacitance than the input, it rises faster and the effective t_{PLH} is negative.

There is a propagation delay, t_{PHL} , through the connection circuitry for falling waveforms. Figure 2 shows the falling edge waveforms. An external driver pulls down the voltage on the side with 50pF capacitance; LTC4304 pulls down the voltage on the opposite side with a delay of 80ns. This delay is always positive and is a function of supply voltage, temperature and the pull-up resistors and equivalent bus capacitances on both sides of the bus. The Typical Performance Characteristics section shows t_{PHL} as a function of temperature and voltage for 10k pull-up resistors and 100pF equivalent capacitance on both sides of the part. Larger output capacitances translate to longer delays. Users must quantify the difference in propagation times for a rising edge versus a falling edge in their systems and adjust setup and hold times accordingly.

Figure 2. Input-Output Connection t_{PHL}

READY Digital Output

The READY pin provides a digital flag which indicates the status of the connection circuitry described previously in the "Connection Circuitry" section. READY is high when the connection circuitry is active, and pulls low when there is not a valid connection. The pin is driven by an open drain pull-down capable of sinking 3mA while holding 0.4V on the pin. Connect a resistor of 10k to V_{CC} to provide the pull-up.

FAULT Digital Output

The FAULT pin provides a digital flag which is low when SDAOUT and SCLOUT have not both been high within 30ms (typical). The pin is driven by an open drain pull-down capable of sinking 3mA while holding 0.4V on the pin. Connect a resistor of 10k to V_{CC} to provide the pull-up.

ENABLE

When the ENABLE pin is driven below 0.8V with respect to the LTC4304's ground, the backplane side is disconnected from the card side, and the READY pin is internally pulled low. When the pin is driven above 2V, the part waits for data transactions on both the backplane and card sides to be complete (as described in the Start-Up section) before connecting the two sides. At this time the internal pulldown on READY releases. When ENABLE is low, automatic clocking is disabled.

OPERATION

A rising edge on ENABLE after a stuck bus condition has occurred forces a connection between SDAIN, SDAOUT and SCLIN, SCLOUT even if bus idle conditions are not met. At this time the internal 30ms timer is reset but not disabled.

Rise Time Accelerators

Once connection has been established, rise time accelerator circuits on all four SDA and SCL pins are activated (assuming accelerators are enabled, see $\overline{ACC}$ pin description). These allow the use of a large pull-up resistor to

reduce power consumption, or bus capacitance beyond that specified in I²C, while still meeting system rise time requirements. During positive bus transitions, the LTC4304 switches in 3.5mA (typical) of current to quickly slew the SDA and SCL lines once their DC voltages exceed 0.8V. Choose a pull-up resistor so that the bus will rise on its own at a rate of at least 0.8V/ μ s to guarantee activation of the accelerators. Rise time accelerators turn off when SDA and SCL lines are approximately 1V below V_{CC} . Rise time accelerators are automatically disabled during automatic clocking.

APPLICATIONS INFORMATION

Resistor Pull-Up Selection

The system pull-up resistors must be strong enough to provide a positive slew rate of 0.8V/ μ s on the SDA and SCL pins, in order to activate the rise time accelerators during rising edges. Choose maximum resistor value $R_{PULL-UP(MAX)}$ using the formula:

$$R_{PULLUP(MAX)}[k\Omega] = \frac{(V_{BUS(MIN)} - 0.8V) \cdot 1250[ns/V]}{C_{BUS}[pF]}$$

where V_{BUSMIN} is the minimum operating pull-up supply voltage, and C_{BUS} the total capacitance on respective bus line.

For example, assume $V_{BUS} = V_{CC} = 3.3V$, and assuming $\pm 10\%$ supply tolerance, $V_{BUSMIN} = 2.97V$. With $C_{BUS} = 100pF$, $R_{PULL-UP, MAX} = 27.1k$. Therefore a smaller pull-up resistor than 27.1k must be used, so 10k works fine.

Live Insertion and Capacitance Buffering Application

Figures 3 through 6 illustrate applications of the LTC4304 that take advantage of both its Hot SwapTM controlling and capacitance buffering features. In all of these applications, note that if the I/O cards were plugged directly into the backplane without the LTC4304 buffer, all of the backplane and card capacitances would add directly together, making rise- and fall-time requirements difficult to meet. Placing a LTC4304 on the edge of each card, however, isolates the card capacitance from the backplane. For a given I/O card,

the LTC4304 drives the capacitance on the card side and the backplane must drive only the digital input capacitance of the LTC4304, which is less than 10pF.

In most applications the LTC4304 will be used with a staggered connector where V_{CC} and GND will be long pins. SDA and SCL are medium length pins to ensure that the V_{CC} and GND pins make contact first. This will allow the precharge circuitry to be activated on SDA and SCL before they make contact. ENABLE is a short pin that is pulled down when not connected. This is to ensure that the connection between the backplane and the cards data and clock busses is not enabled until the transients associated with live insertion have settled.

Figure 3 shows the LTC4304 in a CompactPCITM configuration. Connect V_{CC} and ENABLE to the output of one of the CompactPCI power supply Hot Swap circuits. Use a pull-up resistor to ENABLE for a card side enable/disable. V_{CC} is monitored by a filtered UVLO circuit. With the V_{CC} voltage powering up after all the other pins have established connection, the UVLO circuit ensures that the backplane and the card data and clock busses are not connected until the transients associated with live insertion have settled. Owing to their small capacitance, the SDAIN and SCLIN pins cause minimal disturbance on the backplane busses when they make contact with the connector.

Hot Swap is a trademark of Linear Technology Corporation.

APPLICATIONS INFORMATION

Figure 3. Inserting Multiple I/O Cards into a Live Backplane Using the LTC4304 in a CompactPCI System

APPLICATIONS INFORMATION

Figure 4 shows the LTC4304 in a PCI application where all of the pins have the same length. In this case, a RC filter circuit on the I/O card with a product of 10ms provides a

filter to prevent the LTC4304 from becoming activated until the transients associated with live insertion have settled. Connect the capacitor between ENABLE and GND, and the resistor from V_{CC} to ENABLE.

Figure 4. Inserting Multiple I/O Cards into a Live Backplane Using the LTC4304 in a PCI System

APPLICATIONS INFORMATION

Supply Independent Operation

Figure 5 illustrates applications of the LTC4304 with different bus pull up and V_{CC} voltages, demonstrating its ability to recognize and buffer bus data levels that are above or below its V_{CC} supply voltage. In applications where V_{CC} voltage is greater than bus pull-up voltages, rise-time ac-

celerators cannot be used. Float $\overline{ACC}$ in applications where the pull-up voltage on $SDAIN$ and $SCLIN$ is $< V_{CC}$ and the pull-up voltage on $SDAOUT$ and $SCLOUT$ is $\geq V_{CC}$. Connect $\overline{ACC}$ to ground in applications where V_{CC} is $\leq$ SDA and SCL pull-up voltages. Connect $\overline{ACC}$ to V_{CC} for applications where SDA and SCL pull-up voltages are $\leq V_{CC}$.
