PIN FUNCTIONS

RO: Receiver Output. TTL level logic output. If the receiver is active (\overline{RE} pin low), RO is high if receiver input A \geq B by 200mV. If A \leq B by 200mV, then RO will be low. RO assumes a high impedance output state when \overline{RE} is high or the part is powered off. RO is protected from output shorts from ground to 6V.

\overline{RE} : Receiver Output Enable. TTL level logic input. A logic low on \overline{RE} enables normal operation of the receiver output RO. A logic high level at \overline{RE} places the receiver output pin RO into a high impedance state. If receiver enable \overline{RE} and driver enable DE are both in the disable state, the circuit goes to a low power shutdown state. Placing either \overline{RE} or DE into its active state brings the circuit out of shutdown. Shutdown state is not entered until a 3 μ s delay after both \overline{RE} and DE are disabled, allowing for logic skews in toggling between transmit and receive modes of operation. For CAN bus applications, \overline{RE} should be tied low to prevent the circuit from entering shutdown.

DE: Driver Output Enable. TTL level logic input. A logic high on DE enables normal operation of the driver outputs (Y and Z on LT1791, A and B on LT1785). A logic low level at DE places the driver output pins into a high impedance state. If receiver enable \overline{RE} and driver enable DE are both in the disable state, the circuit goes to a low power shutdown state. Placing either \overline{RE} or DE into its active state brings the circuit out of shutdown. Shutdown state is not entered until a 3 μ s delay after both \overline{RE} and DE are disabled, allowing for logic skews in toggling between transmit and receive modes of operation. For CAN bus operation the DE pin is used for signal input to place the data bus in dominant or recessive states.

DI: Driver Input. TTL level logic input. A logic high at DI causes driver output A or Y to a high state, and output B or Z to a low state. Complementary output states occur for DI low. For CAN bus applications DI should be tied low.

GND: Ground.

Y: Driver Output. The Y driver output is in phase with the driver input DI. In the LT1785 driver output Y is internally connected to receiver input A. The driver output assumes a high impedance state when DE is low, power is off or thermal shutdown is activated. The driver output is protected from shorts between ± 60 V in both active and high impedance modes. For CAN applications, output Y is the CANL output node.

Z: Driver Output. The Z driver output is opposite in phase to the driver input DI. In the LT1785 driver output Z is internally connected to receiver input B. The driver output assumes a high impedance state when DE is low, power is off or thermal shutdown is activated. The driver output is protected from shorts between ± 60 V in both active and high impedance modes. For CAN applications, output Z is the CANH output node.

A: Receiver Input. The A receiver input forces a high receiver output when $V(A) \geq [V(B) + 200\text{mV}]$. $V(A) \leq [V(B) - 200\text{mV}]$ forces a receiver output low. Receiver inputs A and B are protected against voltage faults between ± 60 V. The high input impedance allows up to 128 LT1785 or LT1791 transceivers on one RS485 data bus.

The LT1785A/LT1791A have guaranteed receiver input thresholds $-200\text{mV} < V_{TH} < 0$. Receiver outputs are guaranteed to be in a high state for 0V inputs.

B: Receiver Input. The B receiver input forces a high receiver output when $V(A) \geq [V(B) + 200\text{mV}]$. When $V(A) \leq [V(B) - 200\text{mV}]$, the B receiver forces a receiver output low. Receiver inputs A and B are protected against voltage faults between ± 60 V. The high input impedance allows up to 128 LT1785 or LT1791 transceivers on one RS485 data bus.

The LT1785A/LT1791A have guaranteed receiver input thresholds $-200\text{mV} < V_{TH} < 0$. Receiver outputs are guaranteed to be in a high state for 0V inputs.

V_{CC}: Positive Supply Input. For RS422 or RS485 operation, $4.75\text{V} \leq V_{CC} \leq 5.25\text{V}$. Higher V_{CC} input voltages increase output drive swing. V_{CC} should be decoupled with a 0.1 μ F low ESR capacitor directly at Pin 8 (V_{CC}).

APPLICATIONS INFORMATION

Overvoltage Protection

The LT1785/LT1791 RS485/RS422 transceivers answer an applications need for overvoltage fault tolerance on data networks. Industrial installations may encounter common mode voltages between nodes far greater than the -7V to 12V range specified for compliance to RS485 standards. CMOS RS485 transceivers can be damaged by voltages above their absolute maximum ratings of typically -8V to 12.5V . Replacement of standard RS485 transceiver components with the LT1785 or LT1791 devices eliminates field failures due to overvoltage faults or the use of costly external protection devices. The limited overvoltage tolerance of CMOS RS485 transceivers makes implementation of effective external protection networks difficult without interfering with proper data network performance within the -7V to 12V region of RS485 operation.

The high overvoltage rating of the LT1785/LT1791 facilitates easy extension to almost any level. Simple discrete component networks that limit the receiver input and driver output voltages to less than $\pm 60\text{V}$ can be added to the device to extend protection to any desired level. Figure 11 shows a protection network against faults to the 120VAC line voltage.

The LT1785/LT1791 protection is achieved by using a high voltage bipolar integrated circuit process for the transceivers. The naturally high breakdown voltages of the bipolar process provides protection in powered-off and high impedance conditions. The driver outputs use a foldback current limit design to protect against overvoltage faults while still allowing high current output drive.

ESD Protection

The LT1785/LT1791 I/O pins have on-chip ESD protection circuitry to eliminate field failures caused by discharges to exposed ports and cables in application environments. The

LT1785 pins A and B and the LT1791 driver output pins Y and Z are protected to IEC-1000-4-2 level 2. These pins will survive multiple ESD strikes of $\pm 15\text{kV}$ air discharge or $\pm 4\text{kV}$ contact discharge. Due to their very high input impedance, the LT1791 receiver pins are protected to IEC-1000-4-2 level 2, or $\pm 15\text{kV}$ air and $\pm 4\text{kV}$ contact discharges. This level of ESD protection will guarantee immunity from field failures in all but the most severe ESD environments. The LT1791 receiver input ESD tolerance may be increased to IEC level 4 compliance by adding 2.2k resistors in series with these pins.

Low Power Shutdown

The LT1785/LT1791 have $\overline{\text{RE}}$ and DE logic inputs to control the receive and transmit modes of the transceivers. The $\overline{\text{RE}}$ input allows normal data reception when in the low state. The receiver output goes to a high impedance state when $\overline{\text{RE}}$ is high, allowing multiplexing the RO data line. The DE logic input performs a similar function on the driver outputs. A high state on DE activates the differential driver outputs, a low state places both driver outputs in to high impedance. Tying the $\overline{\text{RE}}$ and DE logic inputs together may be done to allow one logic signal to toggle the transceiver from receive to transmit modes. The DE input is used as the data input in CAN bus applications.

Disabling both the driver and receiver places the device into a low supply current shutdown mode. An internal time delay of $3\mu\text{s}$ minimum prevents entering shutdown due to small logic skews when a toggle between receive and transmit is desired. The recovery time from shutdown mode is typically $12\mu\text{s}$. The user must be careful to allow for this wake-up delay from shutdown mode. To allow full 250kbaud data rate transmission in CAN applications, the $\overline{\text{RE}}$ pin should be tied low to prevent entering shutdown mode.

APPLICATIONS INFORMATION

Slew Limiting for EMI Emissions Control

The LT1785/LT1791 feature controlled driver output slew rates to control high frequency EMI emissions from equipment and data cables. The slew limiting limits data rate operation to 250kbaud. Slew limiting also mitigates the adverse affects of imperfect transmission line termination caused by stubs or mismatched cable. In some low speed, short distance networks, cable termination may be eliminated completely with no adverse effect on data transmission.

Data Network Cable Selection and Termination

Long distance data networks operating at high data transmission rates should use high quality, low attenuation cable with well-matched cable terminations. Short distance networks at low data rates may use much less expensive PVC cable. These cables have characteristic impedances as low as 72Ω . The LT1785/LT1791 output drivers are guaranteed to drive cables as low as 72Ω .
