2. Pin Configuration

Figure 2-1. Pinning DIP16/SO16

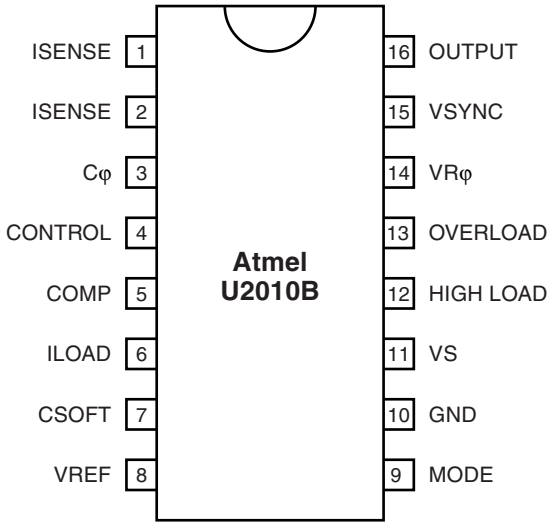

Table 2-1. Pin Description

Pin	Symbol	Function
1	ISENSE	Load current sensing
2	ISENSE	Load current sensing
3	Cφ	Ramp voltage
4	CONTROL	Control input
5	COMP	Compensation output
6	ILOAD	Load current limitation
7	CSOFT	Soft start
8	VREF	Reference voltage
9	MODE	Mode selection
10	GND	Ground
11	VS	Supply voltage
12	HIGH LOAD	High load indication
13	OVERLOAD	Overload indication
14	VRφ	Ramp current adjust
15	VSYNC	Voltage synchronization
16	OUTPUT	Trigger output

3. General Description

3.1 Mains Supply

The Atmel® U2010B contains voltage limiting and can be connected with the mains supply via D_1 and R_1. Supply voltage – between pin 10 and pin 11 – is smoothed by C_1.

In the case of $V_6 \leq 70\%$ of the overload threshold voltage, pins 11 and 12 are connected internally whereby $V_{sat} \leq 1.2V$. When $|V_6| \geq |V_{T70}|$, the supply current flows across D_3.

The series resistance R_1 can be calculated as follows:

$$R_{1max} = \frac{V_{mains} - V_{Smax}}{2 \times I_{tot}}$$

where:

V_{mains} = Mains supply voltage

V_{Smax} = Maximum supply voltage

I_{tot} = Total current consumption = $I_{Smax} + I_x$

I_{Smax} = Maximum current consumption of the IC

I_x = Current consumption of the external components

3.2 Voltage Monitoring

When the voltage is built up, uncontrolled output pulses are avoided by internal voltage monitoring. Apart from that, all latches in the circuit (phase control, load limit regulation) are reset and the soft-start capacitor is short-circuited. This guarantees a specified start-up behavior each time the supply voltage is switched on or after short interruptions of the mains supply. Soft start is isnitiated after the supply voltage has been built up. This behavior guarantees a gentle start-up for the motor and automatically ensures the optimum run-up time.

3.3 Phase Control

The function of the phase control is mainly identical to the well-known IC U211B. The phase angle of the trigger pulse is derived by comparing the ramp voltage V_3, which is mains-synchronized by the voltage detector, with the set value on the control input, pin 4. The slope of the ramp is determined by Cφ and its charging current Iφ. The charging current can be varied using Rφ at pin 14. The maximum phase angle, α_{max}, can also be adjusted by using Rφ (minimum current flow angle φmin), see Figure 7-1 on page 10.

When the potential on pin 3 reaches the set point level of pin 4, a trigger pulse width, t_p, is determined from the value of Cφ (t_p = 9µs/nF). At the same time, a latch is set with the output pulse as long as the automatic retriggering has not been activated. When this happens, no more pulses can be generated in that half cycle. The control input at pin 4 (with respect to pin 10) has an active range from V_8 to -1V. When $V_4 = V_8$, then the phase angle is at its maximum, α_{max}, i.e., the current flow angle is minimum. The minimum phase angle, α_{min}, is set with $V_4 \geq -1V$.

3.4 Automatic Retriggering

The current-detector circuit monitors the state of the triac after triggering by measuring the voltage drop at the triac gate. A current flow through the triac is recognized when the voltage drop exceeds a threshold level of typically 40mV.

If the triac is quenched within the relevant half-wave after triggering (for example owing to low load currents before or after the zero crossing of the current wave, or for commutator motors, owing to brush lifters), the automatic retriggering circuit ensures immediate retriggering, if necessary with a high repetition rate, t_{pp}/t_p, until the triac remains reliably triggered.

3.5 Current Synchronization

Current synchronization fulfils two functions:

– Monitoring the current flow after triggering.
In case the triac extinguishes again or does not switch on, automatic triggering is activated until the triggering is successful.

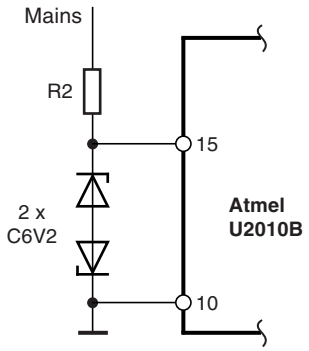
– Avoiding triggering due to an inductive load.
In the case of inductive load operation, the current synchronization ensures that in the new half wave, no pulse will be enabled as long as there is a current available from the previous half wave, which flows from the opposite polarity to the actual supply voltage.

The current synchronization as described above is a special feature of the Atmel® U2010B. The device evaluates the voltage at the pulse output between gate and reference electrode of the triac. As a result, no separate current synchronization input with specified series resistance is necessary.

3.6 Voltage Synchronization with Mains Voltage Compensation

The voltage detector synchronizes the reference ramp with the mains supply voltage. At the same time, the mains-dependent input current at pin 15 is shaped and rectified internally. This current activates the automatic retriggering and at the same time is available at pin 5. By suitable dimensioning, it is possible to obtain the specified compensation effect. Automatic retriggering and mains voltage compensation are not activated until $|V_{15-10}|$ increases to 8V. The resistance $R_{sync.}$ defines the width of the zero voltage cross over pulse, synchronization current, and hence the mains supply voltage compensation current.

Figure 3-1. Suppression of Mains Voltage Compensation and Automatic Retrigger



If the mains voltage compensation and the automatic retriggering are not required, both functions can be suppressed by limiting $|V_{15-10}| \leq 7V$, see Figure 3-1.

3.7 Load-current Compensation

The circuit continuously measures the load current as a voltage drop at resistance R_6. The evaluation and use of both half waves results in a quick reaction to load-current change. Due to the voltage at resistance R_6, there is a difference between both input currents at pins 1 and 2. This difference controls the internal current source, whose positive current values are available at pins 5 and 6. The output current generated at pin 5 contains the difference from the load-current detection and from the mains voltage compensation, see Figure 1-2 on page 2.

The efficient impedance of the set-point network generates a voltage at pin 4. A current, flowing out of pin 5 through R_{10}, modulates this voltage. An increase of mains voltage causes the increase of control angle α, an increase of load current results in a decrease in the control angle. This avoids a decrease in revolution by increasing the load as well as an increase of revolution by the increment of the mains supply voltage.

3.8 Load-current Limitation

The total output load current is available at pin 6. It results in a voltage drop across R_{11}. When the potential of the load current reaches about 70% of the threshold value (V_{T70}), i.e., about 4.35V at pin 6, it switches the high-load comparator and opens the switch between pins 11 and 12. By using an LED between these pins (11 and 12), a high-load indication can be realized.

If the potential at pin 6 increases to about 6.2V (= V_{T100}), it switches the overload comparator. The result is programmable at pin 9 (operation mode).

3.8.1 Mode Selection

a) α_{max} (V_9 = 0)
In this mode of operation, pin 13 switches to $-V_S$ (pin 11) and pin 6 to GND (pin 10) after V_6 has reached the threshold V_{T100}. A soft-start capacitor is then shorted and the control angle is switched to α_{max}. This position is maintained until the supply voltage is switched off. The motor can be started again with the soft-start function when the power is switched on again. As the overload condition switches pin 13 to pin 11, it is possible to use a smaller control angle, α_{max}, by connecting a further resistance between pins 13 and 14.

b) Auto start (pin 9 – open), see Figure 7-8 on page 12
The circuit behaves as described above, with the exception that pin 6 is not connected to GND. If the value of V6 decreases to 25% of the threshold value (V_{T25}), the circuit becomes active again with soft start.

c) I_{max} (V_9 = V_8), see Figure 7-10 on page 13
When V_6 has reached the maximum overload threshold value (i.e., V_6 = V_{T100}), pin 13 is switched to pin 8 (V_{Ref}) through the resistance R (= 2kΩ) without the soft-start capacitor discharging at pin7. With this mode of operation, direct load-current control (I_{max}) is possible.

4. Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Reference point pin 10, unless otherwise specified.

Parameters	Pin	Symbol	Value	Unit
