### 4/15—Revision 0: Initial Version

## SPECIFICATIONS

$V_{IN} = 2.7\text{ V to }5.5\text{ V}$ ,  $T_J = -40^\circ\text{C to }+125^\circ\text{C}$  for minimum/maximum specifications, and  $T_A = 25^\circ\text{C}$  for typical specifications, unless otherwise noted.

Table 2.

Parameter	Symbol	Test Conditions/Comments	Min	Typ	Max	Unit
<b>POWER SUPPLY</b>						
Driver Supply Voltage	$V_{PVIN}$		2.7		5.5	V
Controller Supply Voltage	$V_{VDD}$		2.7		5.5	V
Supply Current	$I_{VDD}$	PWM not switching		3.3	5	mA
Shutdown Current	$I_{SD}$	EN/SY = AGND or VLIM/SD = AGND		350	700	$\mu\text{A}$
Undervoltage Lockout (UVLO)	$V_{UVLO}$	$V_{VDD}$ rising	2.45	2.55	2.65	V
UVLO Hysteresis	$UVLO_{HYST}$		80	90	100	mV
REFERENCE VOLTAGE	$V_{VREF}$	$I_{VREF} = 0\text{ mA to }10\text{ mA}$	2.475	2.50	2.525	V
<b>LINEAR OUTPUT</b>						
Output Voltage	$V_{LDR}$	$I_{LDR} = 0\text{ A}$				
Low				0		V
High				$V_{PVIN}$		V
Maximum Source Current	$I_{LDR\_SOURCE}$	$T_J = -40^\circ\text{C to }+105^\circ\text{C}$	1.5			A
		$T_J = -40^\circ\text{C to }+125^\circ\text{C}$	1.2			A
Maximum Sink Current	$I_{LDR\_SINK}$	$T_J = -40^\circ\text{C to }+105^\circ\text{C}$			1.5	A
		$T_J = -40^\circ\text{C to }+125^\circ\text{C}$			1.2	A
On Resistance		$I_{LDR} = 0.6\text{ A}$

## ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
PVIN to PGNDL (WLCSP)	−0.3 V to +5.75 V
PVIN to PGNDL (WLCSP)	−0.3 V to +5.75 V
PVINL to PGNDL (LFCSP)	−0.3 V to +5.75 V
PVINS to PGNDL (LFCSP)	−0.3 V to +5.75 V
LDR to PGNDL (WLCSP)	−0.3 V to $V_{PVIN}$
LDR to PGNDL (LFCSP)	−0.3 V to $V_{PVINL}$
SW to PGNDL	−0.3 V to +5.75 V
SFB to AGND	−0.3 V to $V_{VDD}$
AGND to PGNDL	−0.3 V to +0.3 V
AGND to PGNDL	−0.3 V to +0.3 V
VLIM/SD to AGND	−0.3 V to $V_{VDD}$
ILIM to AGND	−0.3 V to $V_{VDD}$
VREF to AGND	−0.3 V to +3 V
VDD to AGND	−0.3 V to +5.75 V
IN1P to AGND	−0.3 V to $V_{VDD}$
IN1N to AGND	−0.3 V to $V_{VDD}$
OUT1 to AGND	−0.3 V to +5.75 V
IN2P to AGND	−0.3 V to $V_{VDD}$
IN2N to AGND	−0.3 V to $V_{VDD}$
OUT2 to AGND	−0.3 V to +5.75 V
EN/SY to AGND	−0.3 V to $V_{VDD}$
ITEC to AGND	−0.3 V to +5.75 V
VTEC to AGND	−0.3 V to +5.75 V
Maximum Current	
VREF to AGND	20 mA
OUT1 to AGND	50 mA
OUT2 to AGND	50 mA
ITEC to AGND	50 mA
VTEC to AGND	50 mA
Junction Temperature	125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10 sec)	260°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages, and is based on a 4-layer standard JEDEC board.

Table 4.

Package Type	$\theta_{JA}$	$\theta_{JC}$	Unit
25-Ball WLCSP	48	0.6	°C/W
24-Lead LFCSP	37	1.65	°C/W

### ESD CAUTION

#### ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

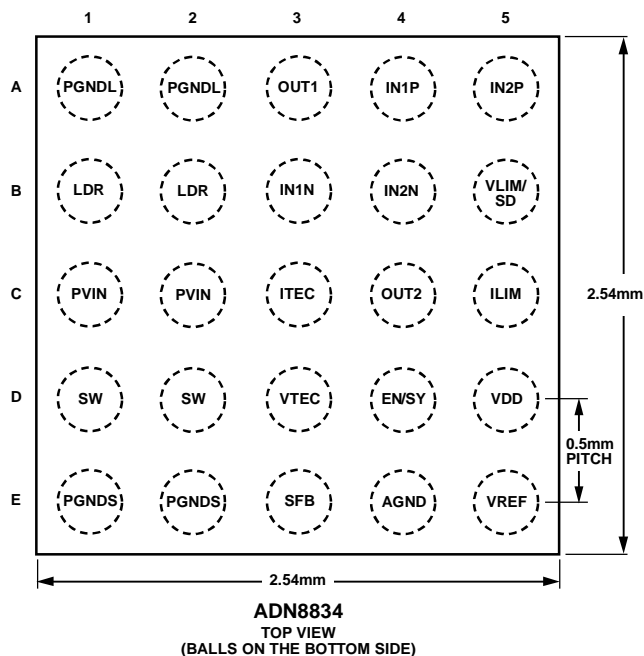

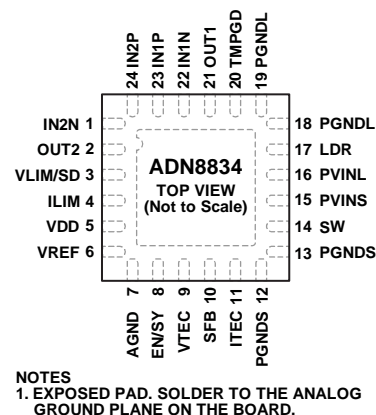

Figure 2. WLCSP Pin Configuration (Top View)

NOTES  
1. EXPOSED PAD, SOLDER TO THE ANALOG GROUND PLANE ON THE BOARD.

12954-200

Figure 3. LFCSP Pin Configuration (Top View)

Table 5. Pin Function Descriptions

Pin No.		Mnemonic	Description
WLCSP	LFCSP		
A1, A2	18, 19	PGNDL	Power Ground of the Linear TEC Controller.
N/A <sup>1</sup>	20	TMPGD	Temperature Good Output.
A3	21	OUT1	Output of the Error Amplifier.
A4	23	IN1P	Noninverting Input of the Error Amplifier.
A5	24	IN2P	Noninverting Input of the Compensation Amplifier.
B1, B2	17	LDR	Output of the Linear TEC Controller.
B3	22	IN1N	Inverting Input of the Error Amplifier.
B4	1	IN2N	Inverting Input of the Compensation Amplifier.
B5	3	VLIM/SD	Voltage Limit/Shutdown. This pin sets the cooling and heating TEC voltage limits. When this pin is pulled low, the device shuts down.
C1, C2	N/A <sup>1</sup>	PVIN	Power Input for the TEC Controller.
N/A <sup>1</sup>	16	PVINL	Power Input for the Linear TEC Driver.
N/A <sup>1</sup>	15	PVINS	Power Input for the PWM TEC Driver.
C3	11	ITEC	TEC Current Output.
C4	2	OUT2	Output of the Compensation Amplifier.
C5	4	ILIM	Current Limit. This pin sets the TEC cooling and heating current limits.
D1, D2	14	SW	Switch Node Output of the PWM TEC Controller.
D3	9	VTEC	TEC Voltage Output.
D4	8	EN/SY	Enable/Synchronization. Set this pin high to enable the device. An external synchronization clock input can be applied to this pin.
D5	5	VDD	Power for the Controller Circuits.
E1, E2	12, 13	PGNDS	Power Ground of the PWM TEC Controller.
E3	10	SFB	Feedback of the PWM TEC Controller Output.
E4	7	AGND	Signal Ground.
E5	6	VREF	2.5 V Reference Output.
N/A <sup>1</sup>	0	EPAD	Exposed Pad. Solder to the analog ground plane on the board.

<sup>1</sup> N/A means not applicable.

## DETAILED FUNCTIONAL BLOCK DIAGRAM

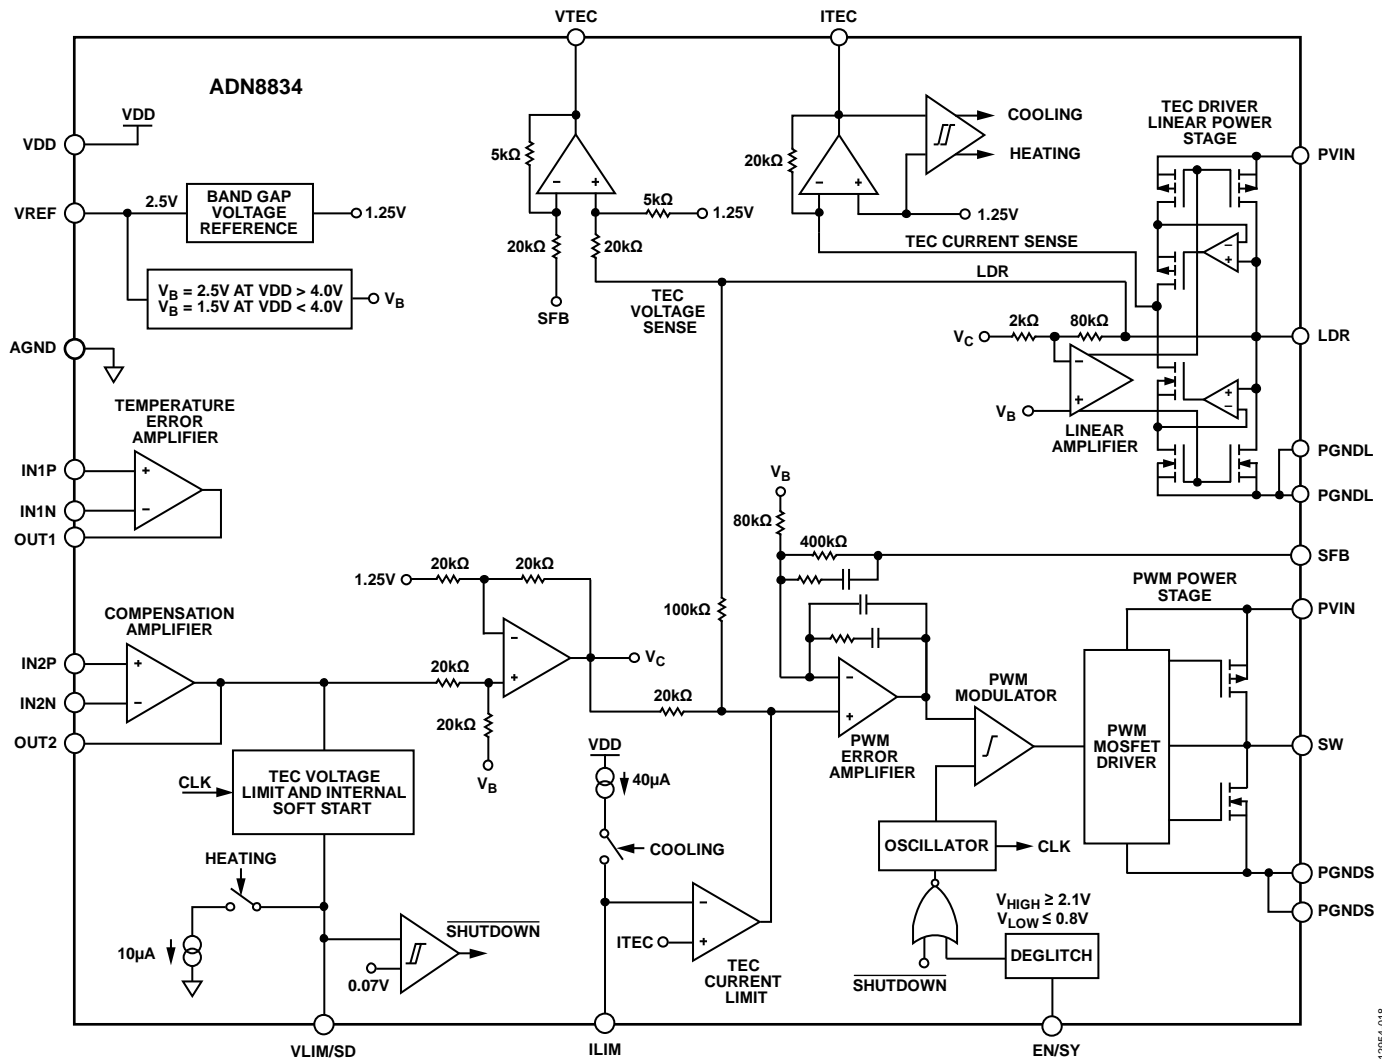

Figure 25. Detailed Functional Block Diagram of the ADN8834 for the WLCSP

## THEORY OF OPERATION

The ADN8834 is a single chip TEC controller that sets and stabilizes a TEC temperature. A voltage applied to the input of the ADN8834 corresponds to the temperature setpoint of the target object attached to the TEC. The ADN8834 controls an internal FET H-bridge whereby the direction of the current fed through the TEC can be either positive (for cooling mode), to pump heat away from the object attached to the TEC, or negative (for heating mode), to pump heat into the object attached to the TEC.

Temperature is measured with a thermal sensor attached to the target object and the sensed temperature (voltage) is fed back to the ADN8834 to complete a closed thermal control loop of the TEC. For the best overall stability, couple the thermal sensor close to the TEC. In most laser diode modules, a TEC and a NTC thermistor are already mounted in the same package to regulate the laser diode temperature.

The TEC is differentially driven in an H-bridge configuration.

The ADN8834 drives its internal MOSFET transistors to provide the TEC current. To provide good power efficiency and zero crossing quality, only one side of the H-bridge uses a PWM driver. Only one inductor and one capacitor are required to filter out the switching frequency. The other side of the H-bridge uses a linear output without requiring any additional circuitry. This proprietary configuration allows the ADN8834 to provide efficiency of >90%. For most applications, a 1  $\mu$ H inductor, a 10  $\mu$ F capacitor, and a switching frequency of 2 MHz maintain less than 1% of the worst-case output voltage ripple across a TEC.

The maximum voltage across the TEC and the current flowing through the TEC are set by using the VLIM/SD and ILIM pins. The maximum cooling and heating currents can be set independently to allow asymmetric heating and cooling limits. For additional details, see the Maximum TEC Voltage Limit section and the Maximum TEC Current Limit section.

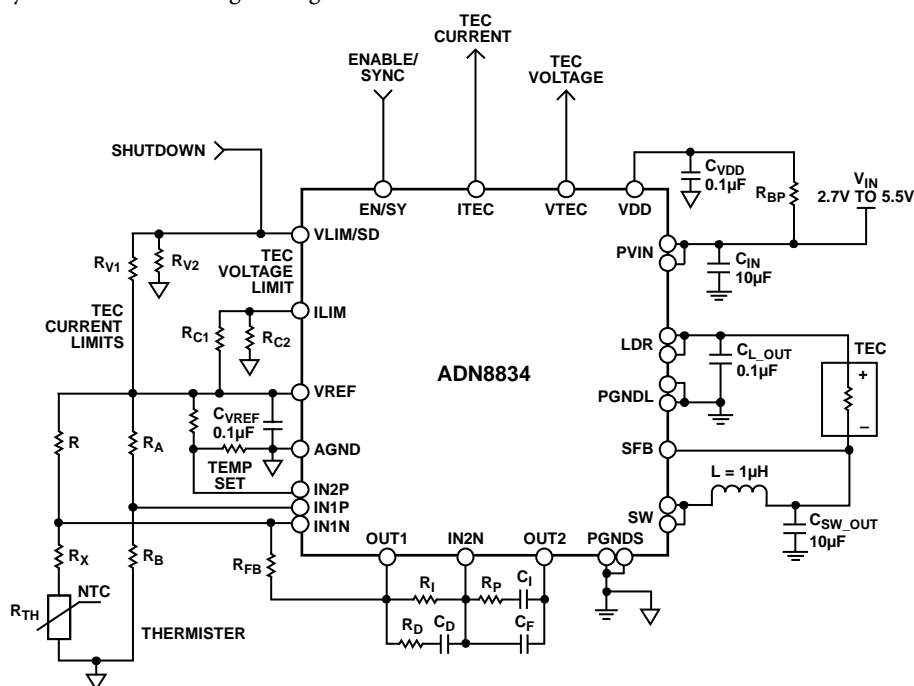

Figure 26. Typical Application Circuit with Analog PID Compensation in a Temperature Control Loop

## ANALOG PID CONTROL

The ADN8834 integrates two self-correcting, auto-zeroing amplifiers (Chopper 1 and Chopper 2). The Chopper 1 amplifier takes a thermal sensor input and converts or regulates the input to a linear voltage output. The OUT1 voltage is proportional to the object temperature. The OUT1 voltage is fed into the compensation amplifier (Chopper 2) and is compared with a temperature setpoint voltage, which creates an error voltage that is proportional to the difference. For autonomous analog temperature control, Chopper 2 can be used to implement a PID network as shown in Figure 27 to set the overall stability and response of the thermal loop. Adjusting the PID network optimizes the step response of the TEC control loop. A compromised settling time and the maximum current ringing become available when this adjustment is done. To adjust the compensation network, see the PID Compensation Amplifier (Chopper 2) section.

## DIGITAL PID CONTROL

The ADN8834 can also be configured for use in a software controlled PID loop. In this scenario, the Chopper 1 amplifier can either be left unused or configured as a thermistor input amplifier connected to an external temperature measurement analog-to-digital converter (ADC). For more information, see the Thermistor Amplifier (Chopper 1) section. If Chopper 1 is left unused, tie IN1N and IN1P to AGND.

The Chopper 2 amplifier is used as a buffer for the external DAC, which controls the temperature setpoint. Connect the DAC to IN2P and short the IN2N and OUT2 pins together. See Figure 27 for an overview of how to configure the ADN8834 external circuitry for digital PID control.

## POWERING THE CONTROLLER

The ADN8834 operates at an input voltage range of 2.7 V to 5.5 V that is applied to the VDD pin and the PVIN pin for the WLCSP (the PVINS pin and PVINL pin for the LFCSP). The VDD pin is the input power for the driver and internal reference. The PVIN input power pins are combined for both the linear and the switching driver. Apply the same input voltage to all power input pins: VDD and PVIN. In some circumstances, an RC low-pass filter can be added optionally between the PVIN for the WLCSP (PVINS and PVINL for the LFCSP) and VDD pins to prevent high frequency noise from entering VDD, as shown in Figure 27. The capacitor and resistor values are typically 10 nF and 100 nF, respectively.

When configuring power supply to the ADN8834, keep in mind that at high current loads, the input voltage may drop substantially due to a voltage drop on the wires between the front-end power supply and the PVIN for the WLCSP (PVINS and PVINL for the LFCSP) pin. Leave a proper voltage margin when designing the front-end power supply to maintain the performance. Minimize the trace length from the power supply to the PVIN for the WLCSP (PVINS and PVINL for the LFCSP) pin to help mitigate the voltage drop.

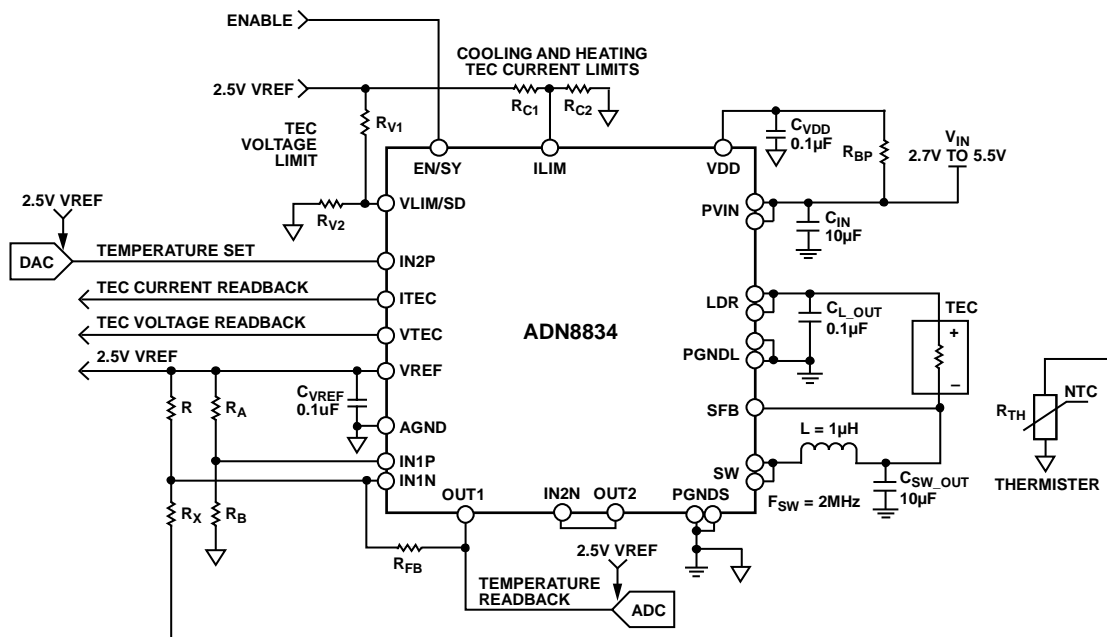

Figure 27. TEC Controller in a Digital Temperature Control Loop (WLCSP)

## ENABLE AND SHUTDOWN

To enable the ADN8834, apply a logic high voltage to the EN/SY pin while the voltage at the VLIM/SD pin is above the maximum shutdown threshold of 0.07 V. If either the EN/SY pin voltage is set to logic low or the VLIM/SD voltage is below 0.07 V, the controller goes into an ultralow current state. The current drawn in shutdown mode is 350  $\mu$ A typically. Most of the current is consumed by the VREF circuit block, which is always on even when the device is disabled or shut down. The device can also be enabled when an external synchronization clock signal is applied to the EN/SY pin, and the voltage at VLIM/SD input is above 0.07 V. Table 6 shows the combinations of the two input signals that are required to enable the ADN8834.

**Table 6. Enable Pin Combinations**

EN/SY Input	VLIM/SD Input	Controller
>2.1 V	>0.07 V	Enabled
Switching between high >2.1 V and low < 0.8 V	>0.07 V	Enabled
<0.8 V	No effect <sup>1</sup>	Shutdown
Floating	No effect <sup>1</sup>	Shutdown
No effect <sup>1</sup>	$\leq 0.07$ V	Shutdown

<sup>1</sup> No effect means this signal has no effect in shutting down or in enabling the device.

## OSCILLATOR CLOCK FREQUENCY

The ADN8834 has an internal oscillator that generates a 2.0 MHz switching frequency for the PWM output stage. This oscillator is active when the enabled voltage at the EN/SY pin is set to a logic level higher than 2.1 V and the VLIM/SD pin voltage is greater than the shutdown threshold of 0.07 V.

### External Clock Operation

The PWM switching frequency of the ADN8834 can be synchronized to an external clock from 1.85 MHz to 3.25 MHz, applied to the EN/SY input pin as shown on Figure 28.

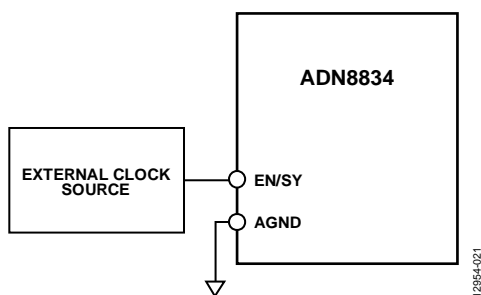

Figure 28. Synchronize to an External Clock

## Connecting Multiple ADN8834 Devices

Multiple ADN8834 devices can be driven from a single master clock signal by connecting the external clock source to the EN/SY pin of each slave device. The input ripple can be greatly reduced by operating the ADN8834 devices 180° out of phase from each other by placing an inverter at one of the EN/SY pins, as shown in Figure 29.

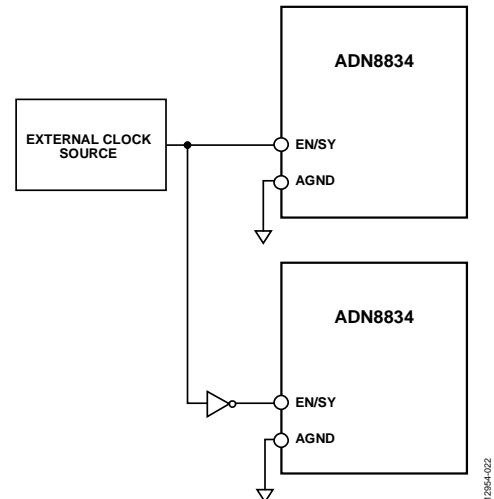

Figure 29. Multiple ADN8834 Devices Driven from a Master Clock

## TEMPERATURE LOCK INDICATOR (LFCSP ONLY)

The TMPGD outputs logic high when the temperature error amplifier output voltage,  $V_{OUT1}$ , reaches the IN2P temperature setpoint (TEMPSET) voltage. The TMPGD has a detection range between 1.46 V and 1.54 V of  $V_{OUT1}$  and hysteresis. The TMPGD function allows direct interfacing either to the microcontrollers or to the supervisory circuitry.

## SOFT START ON POWER-UP

The ADN8834 has an internal soft start circuit that generates a ramp with a typical 150 ms profile to minimize inrush current during power-up. The settling time and the final voltage across the TEC depends on the TEC voltage required by the control voltage of voltage loop. The higher the TEC voltage is, the longer it requires to be built up.

When the ADN8834 is first powered up, the linear side discharges the output of any prebias voltage. As soon as the prebias is eliminated, the soft start cycle begins. During the soft start cycle, both the PWM and linear outputs track the internal soft start ramp until they reach midscale, where the control voltage,  $V_C$ , is equal to the bias voltage,  $V_B$ . From the midscale voltage, the PWM and linear outputs are then controlled by  $V_C$  and diverge from each other until the required differential voltage is developed across the TEC or the differential voltage reaches the voltage limit. The voltage developed across the TEC depends on the control point at that moment in time. Figure 30 shows an example of the soft start in cooling mode. Note that, as both the LDR and SFB voltages increase with the soft start ramp and

approach  $V_B$ , the ramp slows down to avoid possible current overshoot at the point where the TEC voltage starts to build up.

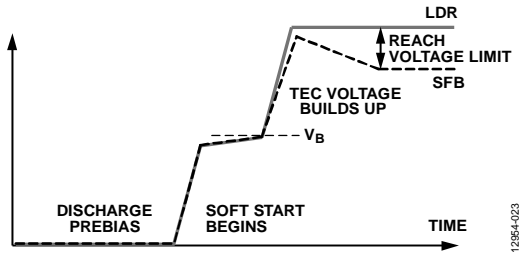

Figure 30. Soft Start Profile in Cooling Mode

## TEC VOLTAGE/CURRENT MONITOR

The TEC real-time voltage and current are detectable at  $V_{TEC}$  and  $I_{TEC}$ , respectively.

### Voltage Monitor

$V_{TEC}$  is an analog voltage output pin with a voltage proportional to the actual voltage across the TEC. A center  $V_{TEC}$  voltage of 1.25 V corresponds to 0 V across the TEC. Convert the voltage at  $V_{TEC}$  and the voltage across the TEC using the following equation:

$$V_{V_{TEC}} = 1.25 \text{ V} + 0.25 \times (V_{LDR} - V_{SFB})$$

### Current Monitor

$I_{TEC}$  is an analog voltage output pin with a voltage proportional to the actual current through the TEC. A center  $I_{TEC}$  voltage of 1.25 V corresponds to 0 A through the TEC. Convert the voltage at  $I_{TEC}$  and the current through the TEC using the following equations:

$$V_{I_{TEC\_COOLING}} = 1.25 \text{ V} + I_{LDR} \times R_{CS}$$

where the current sense gain ( $R_{CS}$ ) is 0.525 V/A.

$$V_{I_{TEC\_HEATING}} = 1.25 \text{ V} - I_{LDR} \times R_{CS}$$

## MAXIMUM TEC VOLTAGE LIMIT

The maximum TEC voltage is set by applying a voltage divider at the VLIM/SD pin to protect the TEC. The voltage limiter operates bidirectionally and allows the cooling limit to be different from the heating limit.

### Using a Resistor Divider to Set the TEC Voltage Limit

Separate voltage limits are set using a resistor divider. The internal current sink circuitry connected to VLIM/SD draws a current when the ADN8834 drives the TEC in a heating direction, which lowers the voltage at VLIM/SD. The current sink is not active when the TEC is driven in a cooling direction; therefore, the TEC heating voltage limit is always lower than the cooling voltage limit.

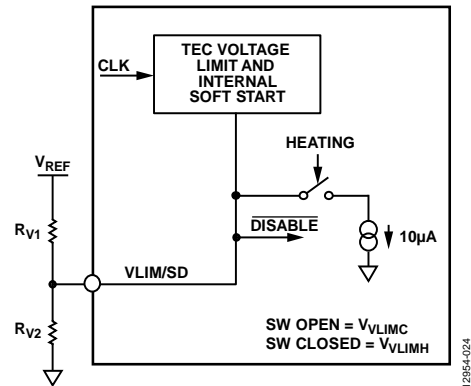

Figure 31. Using a Resistor Divider to Set the TEC Voltage Limit

Calculate the cooling and heating limits using the following equations:

$$V_{VLIM\_COOLING} = V_{REF} \times R_{V2} / (R_{V1} + R_{V2})$$

where  $V_{REF} = 2.5 \text{ V}$ .

$$V_{VLIM\_HEATING} = V_{VLIM\_COOLING} - I_{SINK\_VLIM} \times R_{V1} \parallel R_{V2}$$

where  $I_{SINK\_VLIM} = 10 \mu\text{A}$ .

$$V_{TEC\_MAX\_COOLING} = V_{VLIM\_COOLING} \times A_{VLIM}$$

where  $A_{VLIM} = 2 \text{ V/V}$ .

$$V_{TEC\_MAX\_HEATING} = V_{VLIM\_HEATING} \times A_{VLIM}$$

## MAXIMUM TEC CURRENT LIMIT

To protect the TEC, separate maximum TEC current limits in cooling and heating directions are set by applying a voltage combination at the ILIM pin.

### Using a Resistor Divider to Set the TEC Current Limit

The internal current sink circuitry connected to ILIM draws a 40  $\mu\text{A}$  current when the ADN8834 drives the TEC in a cooling direction, which allows a high cooling current. Use the following equations to calculate the maximum TEC currents:

$$V_{ILIM\_HEATING} = V_{REF} \times R_{C2} / (R_{C1} + R_{C2})$$

where  $V_{REF} = 2.5 \text{ V}$ .

$$V_{ILIM\_COOLING} = V_{ILIM\_HEATING} + I_{SINK\_ILIM} \times R_{C1} \parallel R_{C2}$$

where  $I_{SINK\_ILIM} = 40 \mu\text{A}$ .

$$I_{TEC\_MAX\_COOLING} = \frac{V_{ILIM\_COOLING} - 1.25 \text{ V}}{R_{CS}}$$

where  $R_{CS} = 0.525 \text{ V/A}$ .

$$I_{TEC\_MAX\_HEATING} = \frac{1.25 \text{ V} - V_{ILIM\_HEATING}}{R_{CS}}$$

$V_{ILIM\_HEATING}$  must not exceed 1.2 V and  $V_{ILIM\_COOLING}$  must be more than 1.3 V to leave proper margins between the heating and the cooling modes.

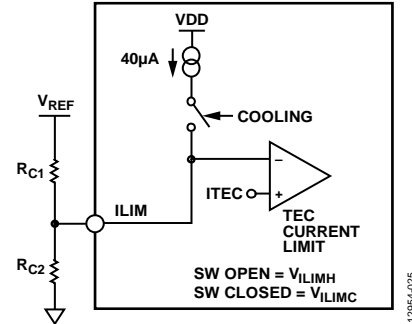

Figure 32. Using a Resistor Divider to Set the TEC Current Limit

## APPLICATIONS INFORMATION

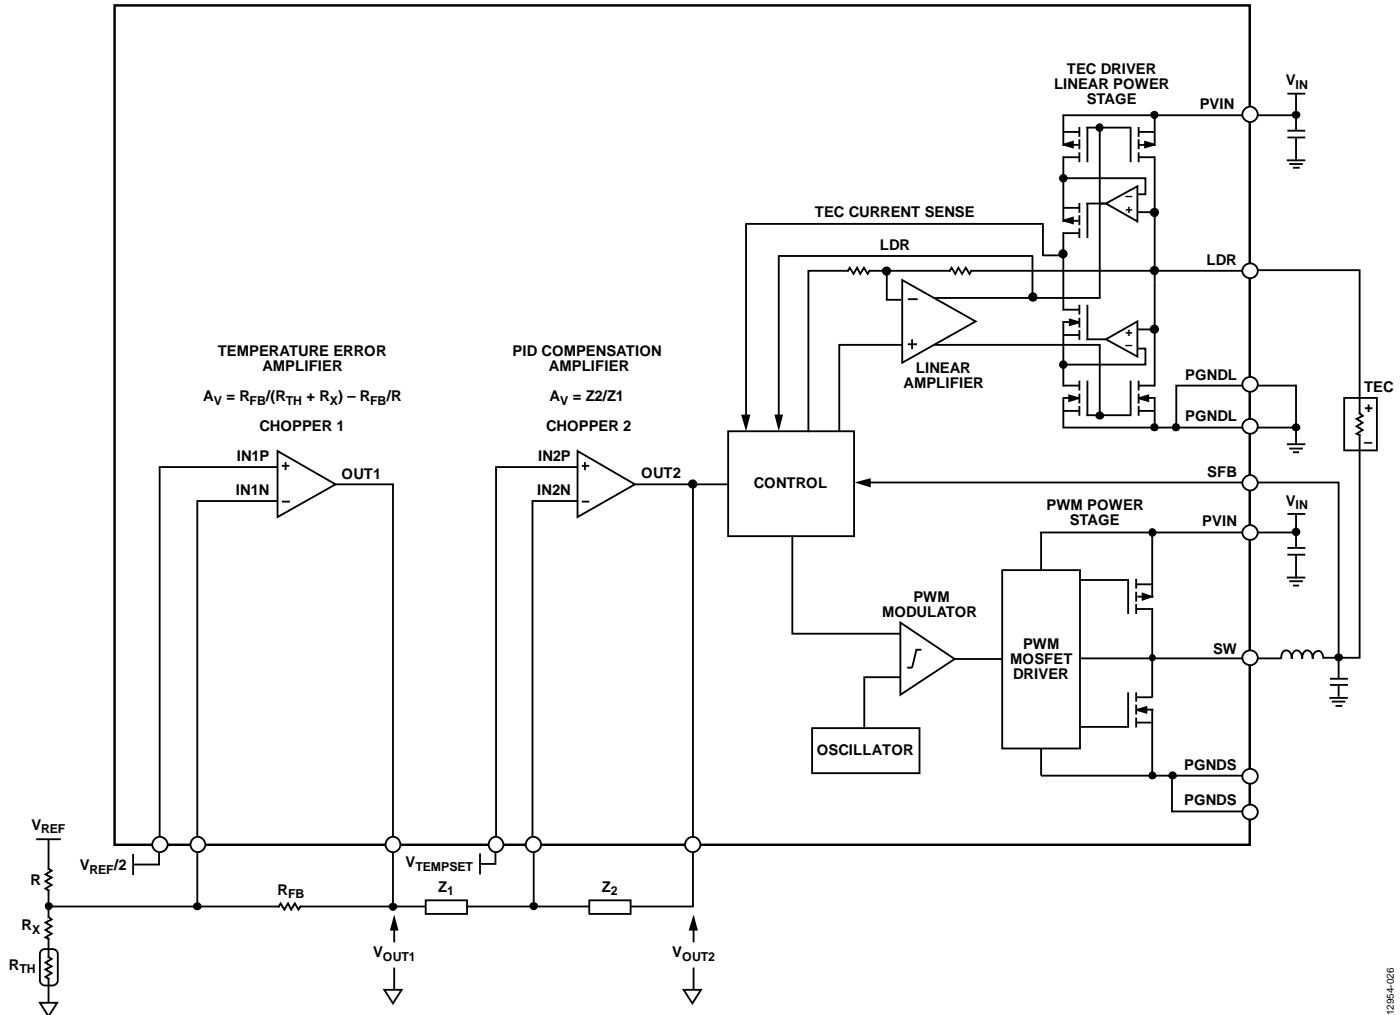

Figure 33. Signal Flow Block Diagram

## SIGNAL FLOW

The ADN8834 integrates two auto-zero amplifiers, defined as the Chopper 1 amplifier and the Chopper 2 amplifier. Both of the amplifiers can be used as standalone amplifiers; therefore, the implementation of temperature control can vary. Figure 33 shows the signal flow through the ADN8834, and a typical implementation of the temperature control loop using the Chopper 1 amplifier and the Chopper 2 amplifier.

In Figure 33, the Chopper 1 and Chopper 2 amplifiers are configured as the thermistor input amplifier and the PID compensation amplifier, respectively. The thermistor input amplifier gains the thermistor voltage, then outputs to the PID compensation amplifier. The PID compensation amplifier then compensates a loop response over the frequency domain.

The output from the compensation loop at OUT2 is fed to the linear MOSFET gate driver. The voltage at LDR is fed with OUT2 into the PWM MOSFET gate driver. Including the internal transistors, the gain of the differential output section is fixed at 5. For details on the output drivers, see the MOSFET Driver Amplifier section.

## THERMISTOR SETUP

The thermistor has a nonlinear relationship to temperature; near optimal linearity over a specified temperature range can be achieved with the proper value of  $R_X$  placed in series with the thermistor.

First, the resistance of the thermistor must be known, where

- $R_{LOW} = R_{TH}$  at  $T_{LOW}$
- $R_{MID} = R_{TH}$  at  $T_{MID}$
- $R_{HIGH} = R_{TH}$  at  $T_{HIGH}$

$T_{LOW}$  and  $T_{HIGH}$  are the endpoints of the temperature range and  $T_{MID}$  is the average. In some cases, with only the  $\beta$  constant available, calculate  $R_{TH}$  using the following equation:

$$R_{TH} = R_R \exp\left\{\beta\left(\frac{1}{T} - \frac{1}{T_R}\right)\right\}$$

where:

$R_{TH}$  is a resistance at  $T$  (K).

$R_R$  is a resistance at  $T_R$  (K).

Calculate  $R_X$  using the following equation:

$$R_X = \left( \frac{R_{LOW} R_{MID} + R_{MID} R_{HIGH} - 2 R_{LOW} R_{HIGH}}{R_{LOW} + R_{HIGH} - 2 R_{MID}} \right)$$

### THERMISTOR AMPLIFIER (CHOPPER 1)

The Chopper 1 amplifier can be used as a thermistor input amplifier. In Figure 33, the output voltage is a function of the thermistor temperature. The voltage at OUT1 is expressed as:

$$V_{OUT1} = \left( \frac{R_{FB}}{R_{TH} + R_X} - \frac{R_{FB}}{R} + 1 \right) \times \frac{V_{REF}}{2}$$

where:

$R_{TH}$  is a thermistor.

$R_X$  is a compensation resistor.

Calculate  $R$  using the following equation:

$$R = R_X + R_{TH\_@\_25^\circ\text{C}}$$

$V_{OUT1}$  is centered around  $V_{REF}/2$  at  $25^\circ\text{C}$ . An average temperature-to-voltage coefficient is  $-25 \text{ mV}/^\circ\text{C}$  at a range of  $5^\circ\text{C}$  to  $45^\circ\text{C}$ .

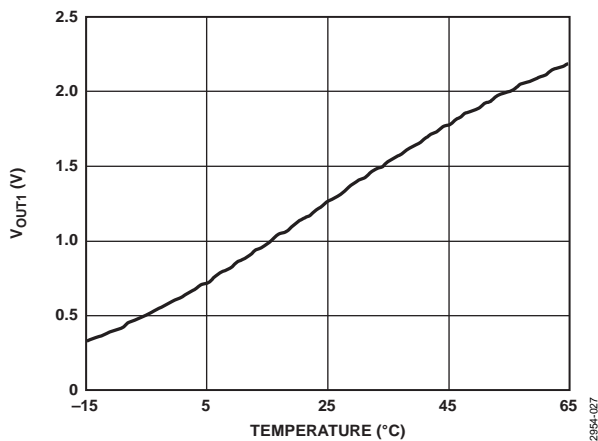

Figure 34.  $V_{OUT1}$  vs. Temperature

### PID COMPENSATION AMPLIFIER (CHOPPER 2)

Use the Chopper 2 amplifier as the PID compensation amplifier. The voltage at OUT1 feeds into the PID compensation amplifier. The frequency response of the PID compensation amplifier is dictated by the compensation network. Apply the temperature set voltage at IN2P. In Figure 39, the voltage at OUT2 is calculated using the following equation:

$$V_{OUT2} = V_{TEMPSET} - \frac{Z2}{Z1} (V_{OUT1} - V_{TEMPSET})$$

where:

$V_{TEMPSET}$  is the control voltage input to the IN2P pin.

$Z1$  is the combination of  $R_p$ ,  $R_D$ , and  $C_D$  (see Figure 35).

$Z2$  is the combination of  $R_p$ ,  $C_i$ , and  $C_F$  (see Figure 35).

The user sets the exact compensation network. This network varies from a simple integrator to proportional-integral (PI), PID (proportional-integral-derivative), or any other type of network. The user also determines the type of compensation and component values because they are dependent on the thermal response of the object and the TEC. One method to empirically determine these

values is to input a step function to IN2P; thus changing the target temperature, and adjust the compensation network to minimize the settling time of the TEC temperature.

A typical compensation network for temperature control of a laser module is a PID loop consisting of a very low frequency pole and two separate zeros at higher frequencies. Figure 35 shows a simple network for implementing PID compensation. To reduce the noise sensitivity of the control loop, an additional pole is added at a higher frequency than that of the zeros. The bode plot of the magnitude is shown in Figure 36. Use the following equation to calculate the unity-gain crossover frequency of the feed-forward amplifier:

$$f_{0dB} = \frac{1}{2\pi R_I C_I} \times \left( \frac{R_{FB}}{R_{TH} + R_X} - \frac{R_{FB}}{R} \right) \times \text{TECGAIN}$$

To ensure stability, the unity-gain crossover frequency must be lower than the thermal time constant of the TEC and thermistor. However, this thermal time constant is sometimes unspecified, making it difficult to characterize. There are many texts written on loop stabilization, and it is beyond the scope of this data sheet to discuss all methods and trade-offs for optimizing compensation networks.

$V_{OUT1}$  is a convenient measure to gauge the thermal instability of the system, which is also known as TEMPOUT. If the thermal loop is in steady state, the TEMPOUT voltage equals the TEMPSET voltage, meaning that the temperature of the controlled object equals the target temperature.

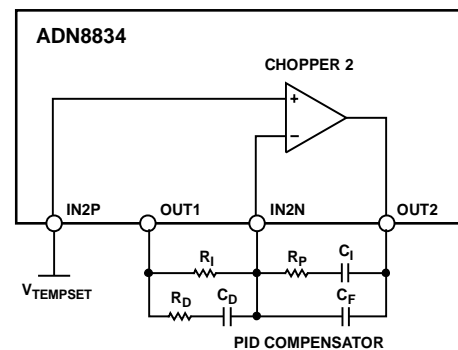

Figure 35. Implementing a PID Compensation Loop

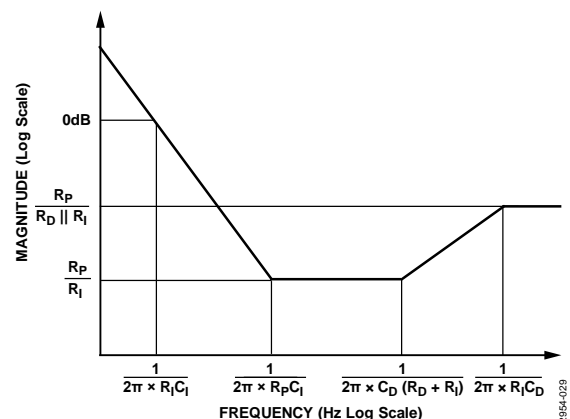

Figure 36. Bode Plot for PID Compensation

## MOSFET DRIVER AMPLIFIERS

The ADN8834 has two separate MOSFET drivers: a switched output or pulse-width modulated (PWM) amplifier, and a high gain linear amplifier. Each amplifier has a pair of outputs that drive the gates of the internal MOSFETs, which, in turn, drive the TEC as shown in Figure 33. A voltage across the TEC is monitored via the SFB and LDR pins. Although both MOSFET drivers achieve the same result, to provide constant voltage and high current, their operation is different. The exact equations for the two outputs are

$$V_{LDR} = V_B - 40(V_{OUT2} - 1.25 \text{ V})$$

$$V_{SFB} = V_{LDR} + 5(V_{OUT2} - 1.25 \text{ V})$$

where:

$V_{OUT2}$  is the voltage at OUT2.

$V_B$  is determined by  $V_{VDD}$  as

$$V_B = 1.5 \text{ V for } V_{VDD} < 4.0 \text{ V}$$

$$V_B = 2.5 \text{ V for } V_{VDD} > 4.0 \text{ V}$$

The compensation network that receives the temperature set voltage and the thermistor voltage fed by the input amplifier determines the voltage at OUT2.  $V_{LDR}$  and  $V_{SFB}$  have a low limit of 0 V and an upper limit of  $V_{VDD}$ . Figure 37, Figure 38, and Figure 39 show the graphs of these equations.

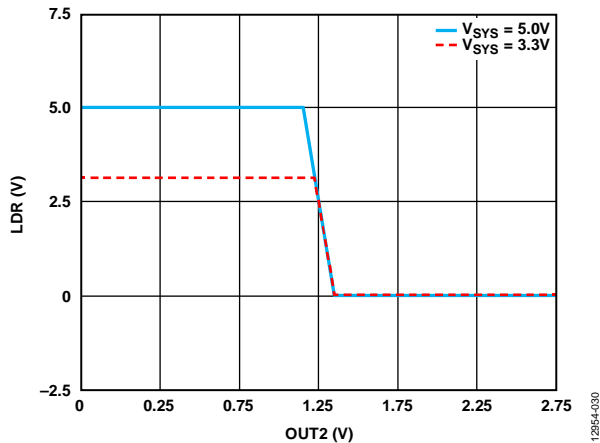

Figure 37. LDR Voltage vs. OUT2 Voltage

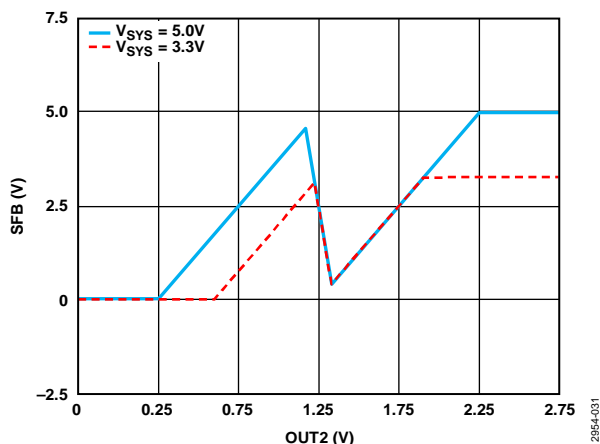

Figure 38. SFB Voltage vs. OUT2 Voltage

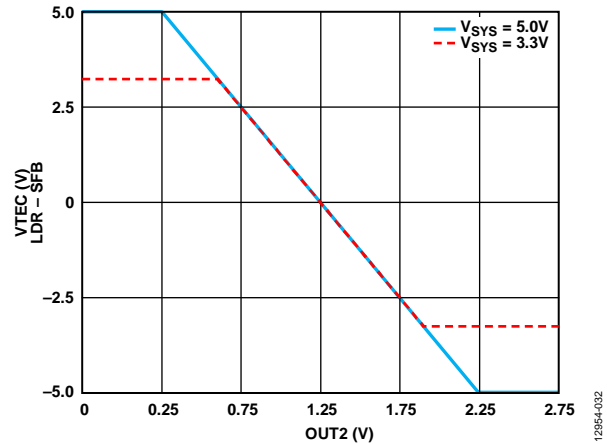

Figure 39. TEC Voltage vs. OUT2 Voltage

## PWM OUTPUT FILTER REQUIREMENTS

A type three compensator internally compensates the PWM amplifier. As the poles and zeros of the compensator are designed and fixed by assuming the resonance frequency of the output LC tank being 50 kHz, the selection of the inductor and the capacitor must follow this guideline to ensure system stability.

### Inductor Selection

The inductor selection determines the inductor current ripple and loop dynamic response. Larger inductance results in smaller current ripple and slower transient response as smaller inductance results in the opposite performance. To optimize the performance, the trade-off must be made between transient response speed, efficiency, and component size. Calculate the inductor value with the following equation:

$$L = \frac{V_{SW\_OUT} \times (V_{IN} - V_{SW\_OUT})}{V_{IN} \times f_{SW} \times \Delta I_L}$$

where:

$V_{SW\_OUT}$  is the PWM amplifier output.

$f_{SW}$  is the switching frequency (2 MHz by default).

$\Delta I_L$  is the inductor current ripple.

A 1  $\mu\text{H}$  inductor is typically recommended to allow reasonable output capacitor selection while maintaining a low inductor current ripple. If lower inductance is required, a minimum inductor value of 0.68  $\mu\text{H}$  is suggested to ensure that the current ripple is set to a value between 30% and 40% of the maximum load current, which is 1.5 A.

Except for the inductor value, the equivalent dc resistance (DCR) inherent in the metal conductor is also a critical factor for inductor selection. The DCR accounts for most of the power loss on the inductor by  $\text{DCR} \times I_{OUT}^2$ . Using an inductor with high DCR degrades the overall efficiency significantly. In addition, there is a conduct voltage drop across the inductor because of the DCR. When the PWM amplifier is sinking current in cooling mode, this voltage drives the minimum voltage of the amplifier higher than  $0.06 \times V_{IN}$  by at least tenth of millivolts. Similarly, the maximum PWM amplifier output voltage is lower than  $0.93 \times V_{IN}$ .

This voltage drop is proportional to the value of the DCR and it reduces the output voltage range at the TEC.

When selecting an inductor, ensure that the saturation current rating is higher than the maximum current peak to prevent saturation. In general, ceramic multilayer inductors are suitable for low current applications due to small size and low DCR. When the noise level is critical, use a shielded ferrite inductor to reduce the electromagnetic interference (EMI).

**Table 7. Recommended Inductors**

Vendor	Value	Device No.	Footprint
Toko	1.0 $\mu\text{H} \pm 20\%$ , 2.6 A (typical)	DFE201612R-H-1R0M	2.0 $\times$ 1.6
Taiyo Yuden	1.0 $\mu\text{H} \pm 20\%$ , 2.2 A (typical)	MAKK2016T1R0M	2.0 $\times$ 1.6
Murata	1.0 $\mu\text{H} \pm 20\%$ , 2.3 A (typical)	LQM2MPN1R0MGH	2.0 $\times$ 1.6

### Capacitor Selection

The output capacitor selection determines the output voltage ripple, transient response, as well as the loop dynamic response of the PWM amplifier output. Use the following equation to select the capacitor:

$$C = \frac{V_{SW\_OUT} \times (V_{IN} - V_{SW\_OUT})}{V_{IN} \times 8 \times L \times (f_{SW})^2 \times \Delta V_{OUT}}$$

Note that the voltage caused by the product of current ripple,  $\Delta I_L$ , and the capacitor equivalent series resistance (ESR) also add up to the total output voltage ripple. Selecting a capacitor with low ESR can increase overall regulation and efficiency performance.

**Table 8. Recommended Capacitors**

Vendor	Value	Device No.	Footprint (mm)
Murata	10 $\mu\text{F} \pm 10\%$ , 10 V	ZRB18AD71A106KE01L	1.6 $\times$ 0.8
Murata	10 $\mu\text{F} \pm 20\%$ , 10 V	GRM188D71A106MA73	1.6 $\times$ 0.8
Taiyo Yuden	10 $\mu\text{F} \pm 20\%$ , 10 V	LMK107BC6106MA-T	1.6 $\times$ 0.8

### INPUT CAPACITOR SELECTION

On the PVIN pin, the amplifiers require an input capacitor to decouple the noise and to provide the transient current to maintain a stable input and output voltage. A 10  $\mu\text{F}$  ceramic capacitor rated at 10 V is the minimum recommended value. Increasing the capacitance reduces the switching ripple that couples into the power supply but increases the capacitor size. Because the current at the input terminal of the PWM amplifier is discontinuous, a capacitor with low effective series inductance (ESL) is preferred to reduce voltage spikes.

In most applications, a decoupling capacitor is used in parallel with the input capacitor. The decoupling capacitor is usually a 100 nF ceramic capacitor with very low ESR and ESL, which provides better noise rejection at high frequency bands.

### POWER DISSIPATION

This section provides guidelines to calculate the power dissipation of the ADN8834. Approximate the total power dissipation in the device by

$$P_{LOSS} = P_{PWM} + P_{LINEAR}$$

where:

$P_{LOSS}$  is the total power dissipation in the ADN8834.

$P_{LINEAR}$  is the power dissipation in the linear regulator.

#### PWM Regulator Power Dissipation

The PWM power stage is configured as a buck regulator and its dominant power dissipation ( $P_{PWM}$ ) includes power switch conduction losses ( $P_{COND}$ ), switching losses ( $P_{SW}$ ), and transition losses ( $P_{TRAN}$ ). Other sources of power dissipation are usually less significant at the high output currents of the application thermal limit and can be neglected in approximation.

Use the following equation to estimate the power dissipation of the buck regulator:

$$P_{LOSS} = P_{COND} + P_{SW} + P_{TRAN}$$

#### Conduction Loss ( $P_{COND}$ )

The conduction loss consists of two parts: inductor conduction loss ( $P_{COND\_L}$ ) and power switch conduction loss ( $P_{COND\_S}$ ).

$$P_{COND} = P_{COND\_L} + P_{COND\_S}$$

Inductor conduction loss is proportional to the DCR of the output inductor, L. Using an inductor with low DCR enhances the overall efficiency performance. Estimate inductor conduction loss by

$$P_{COND\_L} = DCR \times I_{OUT}^2$$

Power switch conduction losses are caused by the flow of the output current through both the high-side and low-side power switches, each of which has its own internal on resistance ( $R_{DS(on)}$ ).

Use the following equation to estimate the amount of power switch conduction loss:

$$P_{COND\_S} = (R_{DS(on)\_HS} \times D + R_{DS(on)\_LS} \times (1 - D)) \times I_{OUT}^2$$

where:

$R_{DS(on)\_HS}$  is the on resistance of the high-side MOSFET.

$D$  is the duty cycle ( $D = V_{OUT}/V_{IN}$ ).

$R_{DS(on)\_LS}$  is the on resistance of the low-side MOSFET.

**Switching Loss ( $P_{SW}$ )**

Switching losses are associated with the current drawn by the controller to turn the power devices on and off at the switching frequency. Each time a power device gate is turned on or off, the controller transfers a charge from the input supply to the gate, and then from the gate to ground. Use the following equation to estimate the switching loss:

$$P_{SW} = (C_{GATE\_HS} + C_{GATE\_LS}) \times V_{IN}^2 \times f_{SW}$$

where:

$C_{GATE\_HS}$  is the gate capacitance of the high-side MOSFET.

$C_{GATE\_LS}$  is the gate capacitance of the low-side MOSFET.

$f_{SW}$  is the switching frequency.

For the ADN8834, the total of ( $C_{GATE\_HS} + C_{GATE\_LS}$ ) is approximately 1 nF.

**Transition Loss ( $P_{TRAN}$ )**

Transition losses occur because the high-side MOSFET cannot turn on or off instantaneously. During a switch node transition, the MOSFET provides all the inductor current. The source-to-drain voltage of the MOSFET is half the input voltage, resulting in power loss. Transition losses increase with both load and input voltage and occur twice for each switching cycle.

Use the following equation to estimate the transition loss:

$$P_{TRAN} = 0.5 \times V_{IN} \times I_{OUT} \times (t_R + t_F) \times f_{SW}$$

where:

$t_R$  is the rise time of the switch node.

$t_F$  is the fall time of the switch node.

For the ADN8834,  $t_R$  and  $t_F$  are both approximately 1 ns.

**Linear Regulator Power Dissipation**

The power dissipation of the linear regulator is given by the following equation:

$$P_{LINEAR} = [(V_{IN} - V_{OUT}) \times I_{OUT}] + (V_{IN} \times I_{GND})$$

where:

$V_{IN}$  and  $V_{OUT}$  are the input and output voltages of the linear regulator.

$I_{OUT}$  is the load current of the linear regulator.

$I_{GND}$  is the ground current of the linear regulator.

Power dissipation due to the ground current is generally small and can be ignored for the purposes of this calculation.

## PCB LAYOUT GUIDELINES

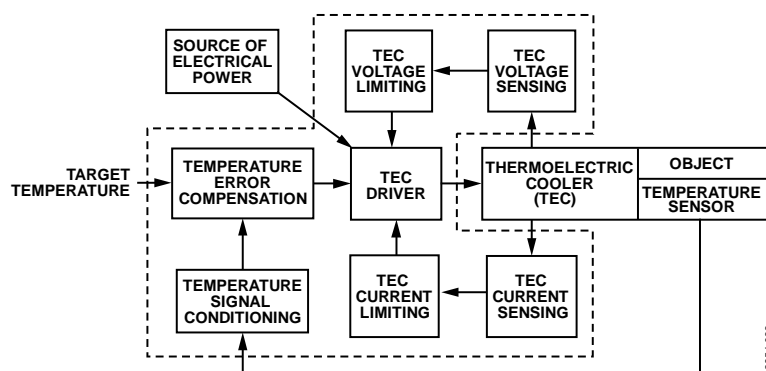

Figure 40. System Block Diagram

### BLOCK DIAGRAMS AND SIGNAL FLOW

The ADN8834 integrates analog signal conditioning blocks, a load protection block, and a TEC controller power stage all in a single IC. To achieve the best possible circuit performance, attention must be paid to keep noise of the power stage from contaminating the sensitive analog conditioning and protection circuits. In addition, the layout of the power stage must be performed such that the IR losses are minimized to obtain the best possible electrical efficiency.

The system block diagram of the ADN8834 is shown in Figure 40.

### GUIDELINES FOR REDUCING NOISE AND MINIMIZING POWER LOSS

Each printed circuit board (PCB) layout is unique because of the physical constraints defined by the mechanical aspects of a given design. In addition, several other circuits work in conjunction with the TEC controller; these circuits have their own layout requirements, so there are always compromises that must be made for a given system. However, to minimize noise and keep power losses to a minimum during the PCB layout process, observe the following guidelines.

#### General PCB Layout Guidelines

Switching noise can interfere with other signals in the system; therefore, the switching signal traces must be placed away from the power stage to minimize the effect. If possible, place the ground plate between the small signal layer and power stage layer as a shield.

Supply voltage drop on traces is also an important consideration because it determines the voltage headroom of the TEC controller at high currents. For example, if the supply voltage from the front-end system is 3.3 V, and the voltage drop on the traces is 0.5 V, PVIN sees only 2.8 V, which limits the maximum voltage of the linear regulator as well as the maximum voltage across the TEC. To mitigate the voltage waste on traces and impedance interconnection, place the ADN8834 and the input decoupling components close to the supply voltage terminal. This placement not only improves the system efficiency but also provides better regulation performance at the output.

To prevent noise signal from circulating through ground plates, reference all of the sensitive analog signals to AGND and connect AGND to PGNDs using only a single point connection. This ensures that the switching currents of the power stage do not flow into the sensitive AGND node.

#### PWM Power Stage Layout Guidelines

The PWM power stage consists of a MOSFET pair that forms a switch mode output that switches current from PVIN to the load via an LC filter. The ripple voltage on the PVIN pin is caused by the discontinuous current switched by the PWM side MOSFETs. This rapid switching causes voltage ripple to form at the PVIN input, which must be filtered using a bypass capacitor. Place a 10  $\mu$ F capacitor as close as possible to the PVIN pin to connect PVIN to PGNDs. Because the 10  $\mu$ F capacitor is sometimes bulky and has higher ESR and ESL, a 100 nF decoupling capacitor is usually used in parallel with it, placed between PVIN and PGNDs.

Because the decoupling is part of the pulsating current loop, which carries high di/dt signals, the traces must be short and wide to minimize the parasitic inductance. As a result, this capacitor is usually placed on the same side of the board as the ADN8834 to ensure short connections. If the layout requires that a 10  $\mu$ F capacitor be on the opposite side of the PCB, use multiple vias to reduce via impedance.

The layout around the SW node is also critical because it switches between PVIN and ground rapidly, which makes this node a strong EMI source. Keep the copper area that connects the SW node to the inductor small to minimize parasitic capacitance between the SW node and other signal traces. This helps minimize noise on the SW node due to excessive charge injection. However, in high current applications, the copper area may be increased reasonably to provide heat sink and to sustain high current flow. Connect the ground side of the capacitor in the LC filter as close as possible to PGNDs to minimize the ESL in the return path.

### Linear Power Stage Layout Guidelines

The linear power stage consists of a MOSFET pair that forms a linear amplifier, which operates in linear mode for very low output currents, and changes to fully enhanced mode for greater output currents.

Because the linear power stage does not switch currents rapidly like the PWM power stage, it does not generate noise currents. However, the linear power stage still requires a minimum amount of bypass capacitance to decouple its input.

Place a 100 nF capacitor that connects from PVIN to PGNDL as close as possible to the PVIN pin.

### Placing the Thermistor Amplifier and PID Components

The thermistor conditioning and PID compensation amplifiers work with very small signals and have gain; therefore, attention must be paid when placing the external components with these circuits.

Place the thermistor conditioning and PID circuit components close to each other near the inputs of Chopper 1 and Chopper 2. Avoid crossing paths between the amplifier circuits and the power stages to prevent noise pickup on the sensitive nodes. Always reference the thermistor to AGND to have the cleanest connection to the amplifier input and to avoid any noise or offset build up.

### EXAMPLE PCB LAYOUT USING TWO LAYERS

Figure 41, Figure 42, and Figure 43 show an example ADN8834 PCB layout that uses two layers. This layout example achieves a small solution size of approximately 20 mm<sup>2</sup> with all of the conditioning circuitry and PID included. Using more layers and blinds via allows the solution size to be reduced even further because more of the discrete components can relocate to the bottom side of the PCB.
