REVISION HISTORY

03/14—Rev. D to Rev. E

Updated Development Tools	21	Added/changed package dimensions to Figure 88 in Outline Dimensions	100
Corrected SPI2 pin count in Port B configuration in Pin Multiplexing	24	Added low Alpha Package model to Ordering Guide	101
Corrected typographical error of parameter name in External DMA Request Timing	58		
Added note to Table 42 in Serial Ports—Enable and Three-State	63		
Corrected t_{WL} and t_{WH} minimum specifications from $t_{SCLK} + 1$ to $1 \times t_{SCLK}$ in Timer Cycle Timing	69		

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

GENERAL DESCRIPTION

The ADSP-BF54x Blackfin® processors are members of the Blackfin family of products, incorporating the Analog Devices/Intel Micro Signal Architecture (MSA). Blackfin processors combine a dual-MAC state-of-the-art signal processing engine, the advantages of a clean, orthogonal RISC-like microprocessor instruction set, and single-instruction, multiple-data (SIMD) multimedia capabilities into a single instruction-set architecture.

Specific performance, memory configurations, and features of ADSP-BF54x Blackfin processors are shown in [Table 1](#).

Table 1. ADSP-BF54x Processor Features

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

The ADSP-BF54x Blackfin processors are completely code- and pin-compatible. They differ only with respect to their performance, on-chip memory, and selection of I/O peripherals. Specific performance, memory, and feature configurations are shown in [Table 1](#).

By integrating a rich set of industry-leading system peripherals and memory, Blackfin processors are the platform of choice for next-generation applications that require RISC-like programmability, multimedia support, and leading-edge signal processing in one integrated package.

LOW POWER ARCHITECTURE

Blackfin processors provide world-class power management and performance. Blackfin processors are designed in a low power and low voltage design methodology and feature on-chip dynamic power management, the ability to vary both the voltage and frequency of operation to significantly lower overall power consumption. Reducing both voltage and frequency can result in a substantial reduction in power consumption as compared to reducing only the frequency of operation. This translates into longer battery life for portable appliances.

SYSTEM INTEGRATION

The ADSP-BF54x Blackfin processors are highly integrated system-on-a-chip solutions for the next generation of embedded network connected applications. By combining industry-standard interfaces with a high performance signal processing core, users can develop cost-effective solutions quickly without the need for costly external components. The system peripherals include a high speed USB OTG (On-the-Go) controller with integrated PHY, CAN 2.0B controllers, TWI controllers, UART ports, SPI ports, serial ports (SPORTs), ATAPI controller, SD/SDIO controller, a real-time clock, a watchdog timer, LCD controller, and multiple enhanced parallel peripheral interfaces.

BLACKFIN PROCESSOR PERIPHERALS

The ADSP-BF54x processors contain a rich set of peripherals connected to the core via several high bandwidth buses, providing flexibility in system configuration as well as excellent overall system performance (see [Figure 1 on Page 1](#)). The general-purpose peripherals include functions such as UARTs, SPI, TWI, timers with pulse width modulation (PWM) and pulse measurement capability, general-purpose I/O pins, a real-time clock, and a watchdog timer. This set of functions satisfies a wide variety of typical system support needs and is augmented by the system expansion capabilities of the part. The ADSP-BF54x processors contain dedicated network communication modules and high speed serial and parallel ports, an interrupt controller for flexible management of interrupts from the on-chip peripherals or external sources, and power management control functions to tailor the performance and power characteristics of the processor and system to many application scenarios.

All of the peripherals, except for general-purpose I/O, CAN, TWI, real-time clock, and timers, are supported by a flexible DMA structure. There are also separate memory DMA channels dedicated to data transfers between the processor's various

memory spaces, including external DDR (either standard or mobile, depending on the device) and asynchronous memory. Multiple on-chip buses running at up to 133 MHz provide enough bandwidth to keep the processor core running along with activity on all of the on-chip and external peripherals.

The ADSP-BF54x Blackfin processors include an on-chip voltage regulator in support of the dynamic power management capability. The voltage regulator provides a range of core voltage levels when supplied from V_{DDEXT} . The voltage regulator can be bypassed at the user's discretion.

BLACKFIN PROCESSOR CORE

As shown in [Figure 2 on Page 5](#), the Blackfin processor core contains two 16-bit multipliers, two 40-bit accumulators, two 40-bit ALUs, four video ALUs, and a 40-bit shifter. The computation units process 8-, 16-, or 32-bit data from the register file.

The compute register file contains eight 32-bit registers. When performing compute operations on 16-bit operand data, the register file operates as 16 independent 16-bit registers. All operands for compute operations come from the multiplexed register file and instruction constant fields.

Each MAC can perform a 16-bit by 16-bit multiply in each cycle, accumulating the results into the 40-bit accumulators. Signed and unsigned formats, rounding, and saturation are supported.

The ALUs perform a traditional set of arithmetic and logical operations on 16- or 32-bit data. In addition, many special instructions are included to accelerate various signal processing tasks. These include bit operations such as field extract and population count, modulo 2^{32} multiply, divide primitives, saturation and rounding, and sign/exponent detection. The set of video instructions include byte alignment and packing operations, 16-bit and 8-bit adds with clipping, 8-bit average operations, and 8-bit subtract/absolute value/accumulate (SAA) operations. Also provided are the compare/select and vector search instructions.

For certain instructions, two 16-bit ALU operations can be performed simultaneously on register pairs (a 16-bit high half and 16-bit low half of a compute register). By also using the second ALU, quad 16-bit operations are possible.

The 40-bit shifter can perform shifts and rotates and is used to support normalization, field extract, and field deposit instructions.

The program sequencer controls the flow of instruction execution, including instruction alignment and decoding. For program flow control, the sequencer supports PC relative and indirect conditional jumps (with static branch prediction), and subroutine calls. Hardware is provided to support zero-overhead looping. The architecture is fully interlocked, meaning that the programmer need not manage the pipeline when executing instructions with data dependencies.

The address arithmetic unit provides two addresses for simultaneous dual fetches from memory. It contains a multiplexed register file consisting of four sets of 32-bit index, modify,

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

length, and base registers (for circular buffering), and eight additional 32-bit pointer registers (for C-style indexed stack manipulation).

Blackfin processors support a modified Harvard architecture in combination with a hierarchical memory structure. Level 1 (L1) memories are those that typically operate at the full processor speed with little or no latency. At the L1 level, the instruction memory holds instructions only. The two data memories hold data, and a dedicated scratchpad data memory stores stack and local variable information.

In addition, multiple L1 memory blocks are provided, offering a configurable mix of SRAM and cache. The memory management unit (MMU) provides memory protection for individual tasks that may be operating on the core and can protect system registers from unintended access.

The architecture provides three modes of operation: user mode, supervisor mode, and emulation mode. User mode has restricted access to certain system resources, thus providing a protected software environment, while supervisor mode has unrestricted access to the system and core resources.

The Blackfin processor instruction set has been optimized so that 16-bit opcodes represent the most frequently used instructions, resulting in excellent compiled code density. Complex DSP instructions are encoded into 32-bit opcodes, representing fully featured multifunction instructions. Blackfin processors support a limited multi-issue capability, where a 32-bit instruction can be issued in parallel with two 16-bit instructions, allowing the programmer to use many of the core resources in a single instruction cycle.

The Blackfin processor assembly language uses an algebraic syntax for ease of coding and readability. The architecture has been optimized for use in conjunction with the C/C++ compiler, resulting in fast and efficient software implementations.

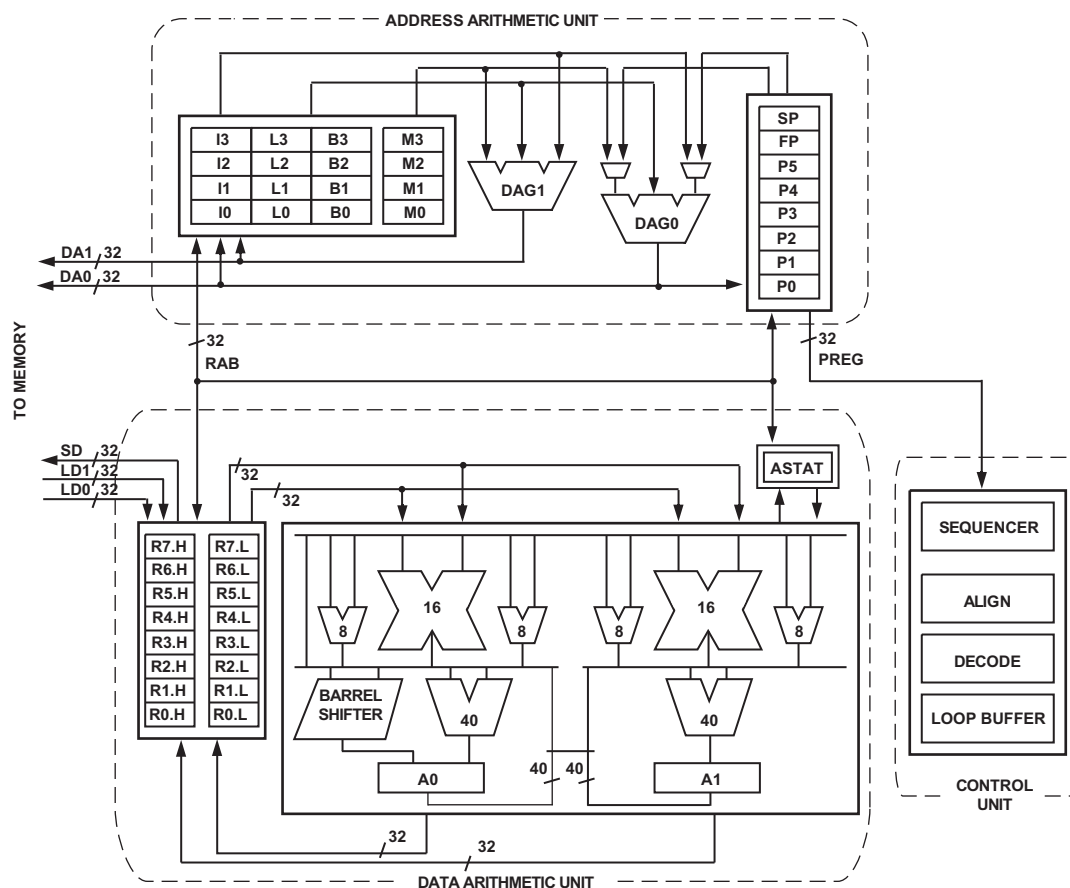

Figure 2. Blackfin Processor Core

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

MEMORY ARCHITECTURE

The ADSP-BF54x processors view memory as a single unified 4G byte address space, using 32-bit addresses. All resources, including internal memory, external memory, and I/O control registers, occupy separate sections of this common address space. The memory portions of this address space are arranged in a hierarchical structure to provide a good cost/performance balance of some very fast, low-latency on-chip memory as cache or SRAM, and larger, lower-cost and performance off-chip memory systems. See [Figure 3 on Page 6](#).

The on-chip L1 memory system is the highest-performance memory available to the Blackfin processor. The off-chip memory system, accessed through the external bus interface unit (EBIU), provides expansion with flash memory, SRAM, and double-rate SDRAM (standard or mobile DDR), optionally accessing up to 768M bytes of physical memory.

Most of the ADSP-BF54x Blackfin processors also include an L2 SRAM memory array which provides up to 128K bytes of high speed SRAM, operating at one half the frequency of the core and with slightly longer latency than the L1 memory banks (for information on L2 memory in each processor, see [Table 1](#)). The L2 memory is a unified instruction and data memory and can hold any mixture of code and data required by the system design. The Blackfin cores share a dedicated low latency 64-bit data path port into the L2 SRAM memory.

The memory DMA controllers (DMAC1 and DMAC0) provide high-bandwidth data-movement capability. They can perform block transfers of code or data between the internal memory and the external memory spaces.

Internal (On-Chip) Memory

The ADSP-BF54x processors have several blocks of on-chip memory providing high bandwidth access to the core.

The first block is the L1 instruction memory, consisting of 64K bytes of SRAM, of which 16K bytes can be configured as a four-way set-associative cache or as SRAM. This memory is accessed at full processor speed.

The second on-chip memory block is the L1 data memory, consisting of 64K bytes of SRAM, of which 32K bytes can be configured as a two-way set-associative cache or as SRAM. This memory block is accessed at full processor speed.

The third memory block is a 4K byte scratchpad SRAM, which runs at the same speed as the L1 memories. It is only accessible as data SRAM and cannot be configured as cache memory.

The fourth memory block is the factory programmed L1 instruction ROM, operating at full processor speed. This ROM is not customer-configurable.

The fifth memory block is the L2 SRAM, providing up to 128K bytes of unified instruction and data memory, operating at one half the frequency of the core.

Finally, there is a 4K byte boot ROM connected as L3 memory. It operates at full SCLK rate.

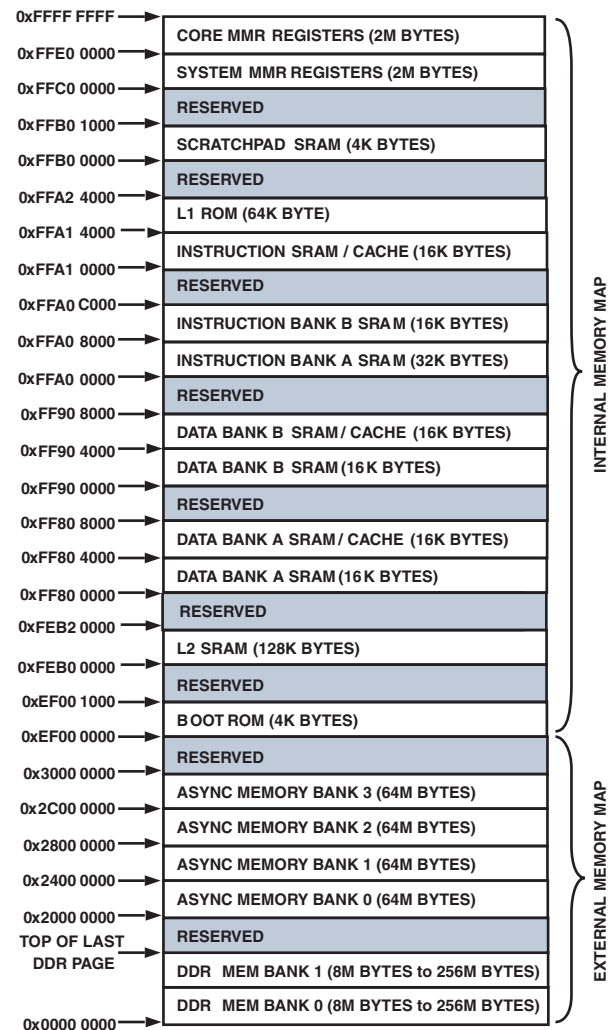

Figure 3. ADSP-BF547/ADSP-BF548/ADSP-BF549 Internal/External Memory Map¹

¹ For ADSP-BF544 processors, L2 SRAM is 64K Bytes (0xFEB00000–0xFEB0FFFF). For ADSP-BF542 processors, there is no L2 SRAM.

External (Off-Chip) Memory

Through the external bus interface unit (EBIU), the ADSP-BF54x Blackfin processors provide glueless connectivity to external 16-bit wide memories, such as DDR and mobile DDR SDRAM, SRAM, NOR flash, NAND flash, and FIFO devices. To provide the best performance, the bus system of the DDR and mobile DDR interface is completely separate from the other parallel interfaces. Furthermore, the DDR controller supports either standard DDR memory or mobile DDR memory. See the [Ordering Guide on Page 101](#) for details. Throughout this document, references to “DDR” are intended to cover both the standard and mobile DDR standards.

The DDR memory controller can gluelessly manage up to two banks of double-rate synchronous dynamic memory (DDR and mobile DDR SDRAM). The 16-bit interface operates at the SCLK frequency, enabling a maximum throughput of 532M bytes/s. The DDR and mobile DDR controller is augmented with a queuing mechanism that performs efficient bursts into the DDR and mobile DDR. The controller is an industry standard DDR and mobile DDR SDRAM controller with each bank supporting from 64M bit to 512M bit device sizes and 4-, 8-, or 16-bit widths. The controller supports up to 256M bytes per external bank. With 2 external banks, the controller supports up to 512M bytes total. Each bank is independently programmable and is contiguous with adjacent banks regardless of the sizes of the different banks or their placement.

Traditional 16-bit asynchronous memories, such as SRAM, EPROM, and flash devices, can be connected to one of the four 64M byte asynchronous memory banks, represented by four memory select strobes. Alternatively, these strobes can function as bank-specific read or write strobes preventing further glue logic when connecting to asynchronous FIFO devices. See the [Ordering Guide on Page 101](#) for a list of specific products that provide support for DDR memory.

In addition, the external bus can connect to advanced flash device technologies, such as:

- Page-mode NOR flash devices
- Synchronous burst-mode NOR flash devices
- NAND flash devices

Customers should consult the [Ordering Guide](#) when selecting a specific ADSP-BF54x component for the intended application. Products that provide support for mobile DDR memory are noted in the ordering guide footnotes.

NAND Flash Controller (NFC)

The ADSP-BF54x Blackfin processors provide a NAND Flash Controller (NFC) as part of the external bus interface. NAND flash devices provide high-density, low-cost memory. However, NAND flash devices also have long random access times, invalid blocks, and lower reliability over device lifetimes. Because of this, NAND flash is often used for read-only code storage. In this case, all DSP code can be stored in NAND flash and then transferred to a faster memory (such as DDR or SRAM) before execution. Another common use of NAND flash is for storage of multimedia files or other large data segments. In this case, a software file system may be used to manage reading and writing of the NAND flash device. The file system selects memory segments for storage with the goal of avoiding bad blocks and equally distributing memory accesses across all address locations. Hardware features of the NFC include:

- Support for page program, page read, and block erase of NAND flash devices, with accesses aligned to page boundaries.
- Error checking and correction (ECC) hardware that facilitates error detection and correction.
- A single 8-bit or 16-bit external bus interface for commands, addresses, and data.

- Support for SLC (single level cell) NAND flash devices unlimited in size, with page sizes of 256 bytes and 512 bytes. Larger page sizes can be supported in software.
- The ability to release external bus interface pins during long accesses.
- Support for internal bus requests of 16 bits or 32 bits.
- A DMA engine to transfer data between internal memory and a NAND flash device.

One-Time-Programmable Memory

The ADSP-BF54x Blackfin processors have 64K bits of one-time-programmable (OTP) non-volatile memory that can be programmed by the developer only one time. It includes the array and logic to support read access and programming. Additionally, its pages can be write protected.

OTP enables developers to store both public and private data on-chip. In addition to storing public and private key data for applications requiring security, it also allows developers to store completely user-definable data such as a customer ID, product ID, or a MAC address. By using this feature, generic parts can be shipped, which are then programmed and protected by the developer within this non-volatile memory. The OTP memory can be accessed through an API provided by the on-chip ROM.

I/O Memory Space

The ADSP-BF54x Blackfin processors do not define a separate I/O space. All resources are mapped through the flat 32-bit address space. On-chip I/O devices have their control registers mapped into memory-mapped registers (MMRs) at addresses near the top of the 4G byte address space. These are separated into two smaller blocks, one containing the control MMRs for all core functions and the other containing the registers needed for setup and control of the on-chip peripherals outside of the core. The MMRs are accessible only in supervisor mode and appear as reserved space to on-chip peripherals.

Bootting

The ADSP-BF54x Blackfin processors contain a small on-chip boot kernel, which configures the appropriate peripheral for booting. If the ADSP-BF54x Blackfin processors are configured to boot from boot ROM memory space, the processor starts executing from the on-chip boot ROM. For more information, see [Bootting Modes on Page 18](#).

Event Handling

The event controller on the ADSP-BF54x Blackfin processors handles all asynchronous and synchronous events to the processors. The ADSP-BF54x Blackfin processors provide event handling that supports both nesting and prioritization. Nesting allows multiple event service routines to be active simultaneously. Prioritization ensures that servicing of a higher-priority event takes precedence over servicing of a lower-priority event.

The controller provides support for five different types of events:

- Emulation. An emulation event causes the processor to enter emulation mode, allowing command and control of the processor via the JTAG interface.
- Reset. This event resets the processor.
- Non-maskable interrupt (NMI). The NMI event can be generated by the software watchdog timer or by the $\overline{\text{NMI}}$ input signal to the processor. The NMI event is frequently used as a power-down indicator to initiate an orderly shut-down of the system.
- Exceptions. Events that occur synchronously to program flow (that is, the exception is taken before the instruction is allowed to complete). Conditions such as data alignment violations and undefined instructions cause exceptions.
- Interrupts. Events that occur asynchronously to program flow. They are caused by input pins, timers, and other peripherals, as well as by an explicit software instruction.

Each event type has an associated register to hold the return address and an associated return-from-event instruction. When an event is triggered, the state of the processor is saved on the supervisor stack.

The ADSP-BF54x Blackfin processor event controller consists of two stages, the core event controller (CEC) and the system interrupt controller (SIC). The core event controller works with the system interrupt controller to prioritize and control all system events. Conceptually, interrupts from the peripherals enter into the SIC and are then routed directly into the general-purpose interrupts of the CEC.

Core Event Controller (CEC)

The CEC supports nine general-purpose interrupts (IVG15–7), in addition to the dedicated interrupt and exception events. Of these general-purpose interrupts, the two lowest-priority interrupts (IVG15–14) are recommended to be reserved for software interrupt handlers, leaving seven prioritized interrupt inputs to support the peripherals of the ADSP-BF54x Blackfin processors. Table 3 describes the inputs to the CEC, identifies their names in the event vector table (EVT), and lists their priorities.

System Interrupt Controller (SIC)

The system interrupt controller provides the mapping and routing of events from the many peripheral interrupt sources to the prioritized general-purpose interrupt inputs of the CEC. Although the ADSP-BF54x Blackfin processors provide a default mapping, the user can alter the mappings and priorities of interrupt events by writing the appropriate values into the interrupt assignment registers (SIC_IARx). The *ADSP-BF54x Hardware Reference Manual*, “System Interrupts” chapter describes the inputs into the SIC and the default mappings into the CEC.

Table 3. Core Event Controller (CEC)

Priority (0 is Highest)	Event Class	EVT Entry
0	Emulation/Test Control	EMU
1	Reset	RST
2	Nonmaskable Interrupt	NMI
3	Exception	EVX
4	Reserved	—
5	Hardware Error	IVHW
6	Core Timer	IVTMR
7	General Interrupt 7	IVG7
8	General Interrupt 8	IVG8
9	General Interrupt 9	IVG9
10	General Interrupt 10	IVG10
11	General Interrupt 11	IVG11
12	General Interrupt 12	IVG12
13	General Interrupt 13	IVG13
14	General Interrupt 14	IVG14
15	General Interrupt 15	IVG15

Event Control

The ADSP-BF54x Blackfin processors provide the user with a very flexible mechanism to control the processing of events. In the CEC, three registers are used to coordinate and control events. Each register is 16 bits wide:

- CEC interrupt latch register (ILAT). The ILAT register indicates when events have been latched. The appropriate bit is set when the processor has latched the event and cleared when the event has been accepted into the system. This register is updated automatically by the controller, but it may be written only when its corresponding IMASK bit is cleared.
- CEC interrupt mask register (IMASK). The IMASK register controls the masking and unmasking of individual events. When a bit is set in the IMASK register, that event is unmasked and is processed by the CEC when asserted. A cleared bit in the IMASK register masks the event, preventing the processor from servicing the event even though the event may be latched in the ILAT register. This register may be read or written while in supervisor mode. Note that general-purpose interrupts can be globally enabled and disabled with the STI and CLI instructions, respectively.
- CEC interrupt pending register (IPEND). The IPEND register keeps track of all nested events. A set bit in the IPEND register indicates that the event is currently active or nested at some level. This register is updated automatically by the controller but may be read while in supervisor mode.

The SIC allows further control of event processing by providing three 32-bit interrupt control and status registers. Each register contains a bit corresponding to each of the peripheral interrupt events shown in the *ADSP-BF54x Hardware Reference Manual*, “System Interrupts” chapter.

- SIC interrupt mask registers (SIC_IMASKx). These registers control the masking and unmasking of each peripheral interrupt event. When a bit is set in a register, that peripheral event is unmasked and is processed by the system when asserted. A cleared bit in the register masks the peripheral event, preventing the processor from servicing the event.
- SIC interrupt status registers (SIC_ISRx). As multiple peripherals can be mapped to a single event, these registers allow the software to determine which peripheral event source triggered the interrupt. A set bit indicates the peripheral is asserting the interrupt, and a cleared bit indicates the peripheral is not asserting the event.
- SIC interrupt wakeup enable registers (SIC_IWRx). By enabling the corresponding bit in this register, a peripheral can be configured to wake up the processor, should the core be idled or in Sleep mode when the event is generated. (For more information, see [Dynamic Power Management on Page 15](#).)

Because multiple interrupt sources can map to a single general-purpose interrupt, multiple pulse assertions can occur simultaneously, before or during interrupt processing for an interrupt event already detected on this interrupt input. The IPEND register contents are monitored by the SIC as the interrupt acknowledgement.

The appropriate ILAT register bit is set when an interrupt rising edge is detected. (Detection requires two core clock cycles.) The bit is cleared when the respective IPEND register bit is set. The IPEND bit indicates that the event has entered into the processor pipeline. At this point the CEC recognizes and queues the next rising edge event on the corresponding event input. The minimum latency from the rising edge transition of the general-purpose interrupt to the IPEND output asserted is three core clock cycles; however, the latency can be much higher, depending on the activity within and the state of the processor.

DMA CONTROLLERS

ADSP-BF54x Blackfin processors have multiple, independent DMA channels that support automated data transfers with minimal overhead for the processor core. DMA transfers can occur between the ADSP-BF54x processors' internal memories and any of the DMA-capable peripherals. Additionally, DMA transfers can be accomplished between any of the DMA-capable peripherals and external devices connected to the external memory interfaces, including DDR and asynchronous memory controllers.

While the USB controller and MXVR have their own dedicated DMA controllers, the other on-chip peripherals are managed by two centralized DMA controllers, called DMAC1 (32-bit) and DMAC0 (16-bit). Both operate in the SCLK domain. Each DMA controller manages 12 independent peripheral DMA channels, as well as two independent memory DMA streams. The DMAC1 controller masters high-bandwidth peripherals over a dedicated 32-bit DMA access bus (DAB32). Similarly, the DMAC0 controller masters most serial interfaces over the 16-bit

DAB16 bus. Individual DMA channels have fixed access priority on the DAB buses. DMA priority of peripherals is managed by a flexible peripheral-to-DMA channel assignment scheme.

All four DMA controllers use the same 32-bit DCB bus to exchange data with L1 memory. This includes L1 ROM, but excludes scratchpad memory. Fine granulation of L1 memory and special DMA buffers minimize potential memory conflicts when the L1 memory is accessed simultaneously by the core. Similarly, there are dedicated DMA buses between the external bus interface unit (EBIU) and the three DMA controllers (DMAC1, DMAC0, and USB) that arbitrate DMA accesses to external memories and the boot ROM.

The ADSP-BF54x Blackfin processors' DMA controllers support both 1-dimensional (1D) and 2-dimensional (2D) DMA transfers. DMA transfer initialization can be implemented from registers or from sets of parameters called descriptor blocks.

The 2D DMA capability supports arbitrary row and column sizes up to 64K elements by 64K elements, and arbitrary row and column step sizes up to $\pm 32K$ elements. Furthermore, the column step size can be less than the row step size, allowing implementation of interleaved data streams. This feature is especially useful in video applications where data can be de-interleaved on the fly.

Examples of DMA types supported by the ADSP-BF54x Blackfin processors' DMA controllers include:

- A single, linear buffer that stops upon completion
- A circular, auto-refreshing buffer that interrupts on each full or fractionally full buffer
- 1D or 2D DMA using a linked list of descriptors
- 2D DMA using an array of descriptors, specifying only the base DMA address within a common page

In addition to the dedicated peripheral DMA channels, the DMAC1 and DMAC0 controllers each feature two memory DMA channel pairs for transfers between the various memories of the ADSP-BF54x Blackfin processors. This enables transfers of blocks of data between any of the memories—including external DDR, ROM, SRAM, and flash memory—with minimal processor intervention. Like peripheral DMAs, memory DMA transfers can be controlled by a very flexible descriptor-based methodology or by a standard register-based autobuffer mechanism.

The memory DMA channels of the DMAC1 controller (MDMA2 and MDMA3) can be controlled optionally by the external DMA request input pins. When used in conjunction with the External Bus Interface Unit (EBIU), this handshaked memory DMA (HMDMA) scheme can be used to efficiently exchange data with block-buffered or FIFO-style devices connected externally. Users can select whether the DMA request pins control the source or the destination side of the memory DMA. It allows control of the number of data transfers for memory DMA. The number of transfers per edge is programmable. This feature can be programmed to allow memory DMA to have an increased priority on the external bus relative to the core.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Host DMA Port Interface

The host DMA port (HOSTDP) facilitates a host device external to the ADSP-BF54x Blackfin processors to be a DMA master and transfer data back and forth. The host device always masters the transactions, and the processor is always a DMA slave device.

The HOSTDP is enabled through the peripheral access bus. Once the port has been enabled, the transactions are controlled by the external host. The external host programs standard DMA configuration words in order to send/receive data to any valid internal or external memory location. The host DMA port controller includes the following features:

- Allows an external master to configure DMA read/write data transfers and read port status
- Uses a flexible asynchronous memory protocol for its external interface
- Allows an 8- or 16-bit external data interface to the host device
- Supports half-duplex operation
- Supports little/big endian data transfers
- Acknowledge mode allows flow control on host transactions
- Interrupt mode guarantees a burst of FIFO depth host transactions

REAL-TIME CLOCK

The ADSP-BF54x Blackfin processors' real-time clock (RTC) provides a robust set of digital watch features, including current time, stopwatch, and alarm. The RTC is clocked by a 32.768 kHz crystal external to the ADSP-BF54x Blackfin processors. The RTC peripheral has dedicated power supply pins so that it can remain powered up and clocked even when the rest of the processor is in a low-power state. The RTC provides several programmable interrupt options, including interrupt per second, minute, hour, or day clock ticks, interrupt on programmable stopwatch countdown, or interrupt at a programmed alarm time.

The 32.768 kHz input clock frequency is divided down to a 1 Hz signal by a prescaler. The counter function of the timer consists of four counters: a 60-second counter, a 60-minute counter, a 24-hour counter, and a 32,768-day counter.

When enabled, the alarm function generates an interrupt when the output of the timer matches the programmed value in the alarm control register. There are two alarms. The first alarm is for a time of day. The second alarm is for a day and time of that day.

The stopwatch function counts down from a programmed value with one-second resolution. When the stopwatch is enabled and the counter underflows, an interrupt is generated.

Like the other peripherals, the RTC can wake up the ADSP-BF54x processor from sleep mode upon generation of any RTC wakeup event. Additionally, an RTC wakeup event can

wake up the ADSP-BF54x processors from deep sleep mode, and it can wake up the on-chip internal voltage regulator from the hibernate state.

Connect RTC pins RTXI and RTXO with external components as shown in Figure 4.

SUGGESTED COMPONENTS:
ECLIPTEK EC38J (THROUGH-HOLE PACKAGE)
EPSON MC405 12 pF LOAD (SURFACE-MOUNT PACKAGE)
C1 = 22 pF
C2 = 22 pF
R1 = 10 MΩ

NOTE: C1 AND C2 ARE SPECIFIC TO CRYSTAL SPECIFIED FOR X1. CONTACT CRYSTAL MANUFACTURER FOR DETAILS. C1 AND C2 SPECIFICATIONS ASSUME BOARD TRACE CAPACITANCE OF 3 pF.

Figure 4. External Components for RTC

WATCHDOG TIMER

The ADSP-BF54x processors include a 32-bit timer that can be used to implement a software watchdog function. A software watchdog can improve system reliability by forcing the processor to a known state through generation of a hardware reset, non-maskable interrupt (NMI), or general-purpose interrupt if the timer expires before being reset by software. The programmer initializes the count value of the timer, enables the appropriate interrupt, and then enables the timer. Thereafter, the software must reload the counter before it counts to zero from the programmed value. This protects the system from remaining in an unknown state where software, which would normally reset the timer, has stopped running due to an external noise condition or software error.

If configured to generate a hardware reset, the watchdog timer resets both the core and the ADSP-BF54x processors' peripherals. After a reset, software can determine if the watchdog was the source of the hardware reset by interrogating a status bit in the watchdog timer control register.

The timer is clocked by the system clock (SCLK) at a maximum frequency of f_{SCLK} .

TIMERS

There are up to two timer units in the ADSP-BF54x Blackfin processors. One unit provides eight general-purpose programmable timers, and the other unit provides three. Each timer has an external pin that can be configured either as a pulse width modulator (PWM) or timer output, as an input to clock the timer, or as a mechanism for measuring pulse widths and periods of external events. These timers can be synchronized to an external clock input on the TMRx pins, an external clock TMRCLK input pin, or to the internal SCLK.

The timer units can be used in conjunction with the four UARTs and the CAN controllers to measure the width of the pulses in the data stream to provide a software auto-baud detect function for the respective serial channels.

The timers can generate interrupts to the processor core, providing periodic events for synchronization to either the system clock or to a count of external signals.

In addition to the general-purpose programmable timers, another timer is also provided by the processor core. This extra timer is clocked by the internal processor clock and is typically used as a system tick clock for generation of periodic operating system interrupts.

UP/DOWN COUNTER AND THUMBWHEEL INTERFACE

A 32-bit up/down counter is provided that can sense the 2-bit quadrature or binary codes typically emitted by industrial drives or manual thumb wheels. The counter can also operate in general-purpose up/down count modes. Then count direction is either controlled by a level-sensitive input pin or by two edge detectors.

A third input can provide flexible zero marker support and can alternatively be used to input the push-button signal of thumb wheels. All three pins have a programmable debouncing circuit.

An internal signal forwarded to the timer unit enables one timer to measure the intervals between count events. Boundary registers enable auto-zero operation or simple system warning by interrupts when programmable count values are exceeded.

SERIAL PORTS (SPORTS)

The ADSP-BF54x Blackfin processors incorporate up to four dual-channel synchronous serial ports (SPORT0, SPORT1, SPORT2, and SPORT3) for serial and multiprocessor communications. The SPORTs support the following features:

- I²S capable operation.
- Bidirectional operation. Each SPORT has two sets of independent transmit and receive pins, enabling up to eight channels of I²S stereo audio.
- Buffered (8-deep) transmit and receive ports. Each port has a data register for transferring data words to and from other processor components and shift registers for shifting data in and out of the data registers.
- Clocking. Each transmit and receive port can either use an external serial clock or generate its own, in frequencies ranging from ($f_{SCLK}/131,070$) Hz to ($f_{SCLK}/2$) Hz.
- Word length. Each SPORT supports serial data words from 3 to 32 bits in length, transferred most-significant-bit first or least-significant-bit first.
- Framing. Each transmit and receive port can run with or without frame sync signals for each data word. Frame sync signals can be generated internally or externally, active high or low, and with either of two pulse widths and early or late frame sync.

- Companding in hardware. Each SPORT can perform A-law or μ -law companding according to ITU recommendation G.711. Companding can be selected on the transmit and/or receive channel of the SPORT without additional latencies.
- DMA operations with single-cycle overhead. Each SPORT can receive and transmit multiple buffers of memory data automatically. The processor can link or chain sequences of DMA transfers between a SPORT and memory.
- Interrupts. Each transmit and receive port generates an interrupt upon completing the transfer of a data word or after transferring an entire data buffer or buffers through DMA.
- Multichannel capability. Each SPORT supports 128 channels out of a 1024-channel window and is compatible with the H.100, H.110, MVIP-90, and HNVIP standards.

SERIAL PERIPHERAL INTERFACE (SPI) PORTS

The ADSP-BF54x Blackfin processors have up to three SPI-compatible ports that allow the processor to communicate with multiple SPI-compatible devices.

Each SPI port uses three pins for transferring data: two data pins (master output slave input, SPIxMOSI, and master input-slave output, SPIxMISO) and a clock pin (serial clock, SPIxSCK). An SPI chip select input pin (SPIxSS) lets other SPI devices select the processor, and three SPI chip select output pins per SPI port SPIxSELy let the processor select other SPI devices. The SPI select pins are reconfigured general-purpose I/O pins. Using these pins, the SPI ports provide a full-duplex, synchronous serial interface, which supports both master/slave modes and multimaster environments.

The SPI port's baud rate and clock phase/polarities are programmable, and it has an integrated DMA controller, configurable to support transmit or receive data streams. The SPI's DMA controller can only service unidirectional accesses at any given time.

The SPI port's clock rate is calculated as

$$SPI \text{ Clock Rate} = \frac{f_{SCLK}}{2 \times SPI_BAUD}$$

Where the 16-bit SPI_BAUD register contains a value of 2 to 65,535.

During transfers, the SPI port transmits and receives simultaneously by serially shifting data in and out on its two serial data lines. The serial clock line synchronizes the shifting and sampling of data on the two serial data lines.

UART PORTS (UARTS)

The ADSP-BF54x Blackfin processors provide up to four full-duplex universal asynchronous receiver/transmitter (UART) ports. Each UART port provides a simplified UART interface to other peripherals or hosts, supporting full-duplex, DMA-supported, asynchronous transfers of serial data. A UART port

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

includes support for five to eight data bits, one or two stop bits, and none, even, or odd parity. Each UART port supports two modes of operation:

- PIO (programmed I/O). The processor sends or receives data by writing or reading I/O-mapped UART registers. The data is double-buffered on both transmit and receive.
- DMA (direct memory access). The DMA controller transfers both transmit and receive data. This reduces the number and frequency of interrupts required to transfer data to and from memory. Each UART has two dedicated DMA channels, one for transmit and one for receive. These DMA channels have lower default priority than most DMA channels because of their relatively low service rates. Flexible interrupt timing options are available on the transmit side.

Each UART port's baud rate, serial data format, error code generation and status, and interrupts are programmable:

- Supporting bit rates ranging from ($f_{SCLK}/1,048,576$) to (f_{SCLK}) bits per second.
- Supporting data formats from seven to 12 bits per frame.
- Both transmit and receive operations can be configured to generate maskable interrupts to the processor.

The UART port's clock rate is calculated as

$$UART \text{ Clock Rate} = \frac{f_{SCLK}}{16^{(1-EDBO)} \times UART_Divisor}$$

Where the 16-bit UART divisor comes from the `UARTx_DLH` register (most significant 8 bits) and `UARTx_DLL` register (least significant eight bits), and the `EDBO` is a bit in the `UARTx_GCTL` register.

In conjunction with the general-purpose timer functions, auto-baud detection is supported.

UART1 and UART3 feature a pair of `UARTxRTS` (request to send) and `UARTxCTS` (clear to send) signals for hardware flow purposes. The transmitter hardware is automatically prevented from sending further data when the `UARTxCTS` input is de-asserted. The receiver can automatically de-assert its `UARTxRTS` output when the enhanced receive FIFO exceeds a certain high-water level. The capabilities of the UARTs are further extended with support for the Infrared Data Association (IrDA®) Serial Infrared Physical Layer Link Specification (SIR) protocol.

CONTROLLER AREA NETWORK (CAN)

The ADSP-BF54x Blackfin processors offer up to two CAN controllers that are communication controllers that implement the controller area network (CAN) 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is well suited for control applications due to its capability to communicate reliably over a network since the protocol incorporates CRC checking, message error tracking, and fault node confinement.

The ADSP-BF54x Blackfin processors' CAN controllers offer the following features:

- 32 mailboxes (8 receive only, 8 transmit only, 16 configurable for receive or transmit).
- Dedicated acceptance masks for each mailbox.
- Additional data filtering on first two bytes.
- Support for both the standard (11-bit) and extended (29-bit) identifier (ID) message formats.
- Support for remote frames.
- Active or passive network support.
- CAN wakeup from hibernation mode (lowest static power consumption mode).
- Interrupts, including: TX complete, RX complete, error and global.

The electrical characteristics of each network connection are very demanding, so the CAN interface is typically divided into two parts: a controller and a transceiver. This allows a single controller to support different drivers and CAN networks. The ADSP-BF54x Blackfin processors' CAN module represents only the controller part of the interface. The controller interface supports connection to 3.3 V high speed, fault-tolerant, single-wire transceivers.

An additional crystal is not required to supply the CAN clock, as the CAN clock is derived from the processor system clock (SCLK) through a programmable divider.

TWI CONTROLLER INTERFACE

The ADSP-BF54x Blackfin processors include up to two 2-wire interface (TWI) modules for providing a simple exchange method of control data between multiple devices. The modules are compatible with the widely used I²C bus standard. The TWI modules offer the capabilities of simultaneous master and slave operation and support for both 7-bit addressing and multimedia data arbitration. Each TWI interface uses two pins for transferring clock (SCLx) and data (SDAx), and supports the protocol at speeds up to 400K bits/sec. The TWI interface pins are compatible with 5 V logic levels.

Additionally, the ADSP-BF54x Blackfin processors' TWI modules are fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

PORTS

Because of their rich set of peripherals, the ADSP-BF54x Blackfin processors group the many peripheral signals to ten ports—referred to as Port A to Port J. Most ports contain 16 pins, though some have fewer. Many of the associated pins are shared by multiple signals. The ports function as multiplexer controls. Every port has its own set of memory-mapped registers to control port muxing and GPIO functionality.

General-Purpose I/O (GPIO)

Every pin in Port A to Port J can function as a GPIO pin, resulting in a GPIO pin count up to 154. While it is unlikely that all GPIO pins will be used in an application, as all pins have multiple functions, the richness of GPIO functionality guarantees unrestricted pin usage. Every pin that is not used by any function can be configured in GPIO mode on an individual basis.

After reset, all pins are in GPIO mode by default. Since neither GPIO output nor input drivers are active by default, unused pins can be left unconnected. GPIO data and direction control registers provide flexible write-one-to-set and write-one-to-clear mechanisms so that independent software threads do not need to protect against each other because of expensive read-modify-write operations when accessing the same port.

Pin Interrupts

Every port pin on ADSP-BF54x Blackfin processors can request interrupts in either an edge-sensitive or a level-sensitive manner with programmable polarity. Interrupt functionality is decoupled from GPIO operation. Four system-level interrupt channels (PINT0, PINT1, PINT2 and PINT3) are reserved for this purpose. Each of these interrupt channels can manage up to 32 interrupt pins. The assignment from pin to interrupt is not performed on a pin-by-pin basis. Rather, groups of eight pins (half ports) can be flexibly assigned to interrupt channels.

Every pin interrupt channel features a special set of 32-bit memory-mapped registers that enables half-port assignment and interrupt management. This not only includes masking, identification, and clearing of requests, it also enables access to the respective pin states and use of the interrupt latches regardless of whether the interrupt is masked or not. Most control registers feature multiple MMR address entries to write-one-to-set or write-one-to-clear them individually.

PIXEL COMPOSITOR (PIXC)

The pixel compositor (PIXC) provides image overlays with transparent-color support, alpha blending, and color space conversion capabilities for output to TFT LCDs and NTSC/PAL video encoders. It provides all of the control to allow two data streams from two separate data buffers to be combined, blended, and converted into appropriate forms for both LCD panels and digital video outputs. The main image buffer provides the basic background image, which is presented in the data stream. The overlay image buffer allows the user to add multiple foreground text, graphics, or video objects on top of the main image or video data stream.

ENHANCED PARALLEL PERIPHERAL INTERFACE (EPPI)

The ADSP-BF54x Blackfin processors provide up to three enhanced parallel peripheral interfaces (EPPIs), supporting data widths up to 24 bits. The EPPI supports direct connection to TFT LCD panels, parallel analog-to-digital and digital-to-analog converters, video encoders and decoders, image sensor modules and other general-purpose peripherals.

The following features are supported in the EPPI module:

- Programmable data length: 8 bits, 10 bits, 12 bits, 14 bits, 16 bits, 18 bits, and 24 bits per clock.
- Bidirectional and half-duplex port.
- Clock can be provided externally or can be generated internally.
- Various framed and non-framed operating modes. Frame syncs can be generated internally or can be supplied by an external device.
- Various general-purpose modes with zero to three frame syncs for both receive and transmit directions.
- ITU-656 status word error detection and correction for ITU-656 receive modes.
- ITU-656 preamble and status word decode.
- Three different modes for ITU-656 receive modes: active video only, vertical blanking only, and entire field mode.
- Horizontal and vertical windowing for GP 2 and 3 frame sync modes.
- Optional packing and unpacking of data to/from 32 bits from/to 8, 16 and 24 bits. If packing/unpacking is enabled, endianness can be changed to change the order of packing/unpacking of bytes/words.
- Optional sign extension or zero fill for receive modes.
- During receive modes, alternate even or odd data samples can be filtered out.
- Programmable clipping of data values for 8-bit transmit modes.
- RGB888 can be converted to RGB666 or RGB565 for transmit modes.
- Various de-interleaving/interleaving modes for receiving/transmitting 4:2:2 YCrCb data.
- FIFO watermarks and urgent DMA features.
- Clock gating by an external device asserting the clock gating control signal.
- Configurable LCD data enable (DEN) output available on Frame Sync 3.

USB ON-THE-GO DUAL-ROLE DEVICE CONTROLLER

The USB OTG dual-role device controller (USBDRD) provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players, allowing these devices to transfer data using a point-to-point USB connection without the need for a PC host. The USBDRD module can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-the-Go (OTG) supplement to the USB 2.0 specification. In host mode, the USB module supports transfers at high speed (480 Mbps), full speed (12 Mbps), and low speed (1.5 Mbps) rates. Peripheral-only mode supports the high and full speed transfer rates.

The USB clock (USB_XI) is provided through a dedicated external crystal or crystal oscillator. See [Table 62](#) for related timing requirements. If using a fundamental mode crystal to provide the USB clock, connect the crystal between USB_XI and USB_XO with a circuit similar to that shown in [Figure 7](#). Use a parallel-resonant, fundamental mode, microprocessor-grade crystal. If a third-overtone crystal is used, follow the circuit guidelines outlined in [Clock Signals on Page 17](#) for third-overtone crystals.

The USB On-the-Go dual-role device controller includes a Phase Locked Loop with programmable multipliers to generate the necessary internal clocking frequency for USB. The multiplier value should be programmed based on the USB_XI clock frequency to achieve the necessary 480 MHz internal clock for USB high speed operation. For example, for a USB_XI crystal frequency of 24 MHz, the USB_PLLOSC_CTRL register should be programmed with a multiplier value of 20 to generate a 480 MHz internal clock.

ATA/ATAPI-6 INTERFACE

The ATAPI interface connects to CD/DVD and HDD drives and is ATAPI-6 compliant. The controller implements the peripheral I/O mode, the multi-DMA mode, and the Ultra DMA mode. The DMA modes enable faster data transfer and reduced host management. The ATAPI controller supports PIO, multi-DMA, and ultra DMA ATAPI accesses. Key features include:

- Supports PIO modes 0, 1, 2, 3, 4
- Supports multiword DMA modes 0, 1, 2
- Supports ultra DMA modes 0, 1, 2, 3, 4, 5 (up to UDMA 100)
- Programmable timing for ATA interface unit
- Supports CompactFlash cards using true IDE mode

By default, the ATAPI_A0-2 address signals and the ATA-PI_D0-15 data signals are shared on the asynchronous memory interface with the asynchronous memory and NAND flash controllers. The data and address signals can be remapped to GPIO ports F and G, respectively, by setting PORTF_MUX[1:0] to b#01.

KEYPAD INTERFACE

The keypad interface is a 16-pin interface module that is used to detect the key pressed in a 8 × 8 (maximum) keypad matrix. The size of the input keypad matrix is programmable. The interface is capable of filtering the bounce on the input pins, which is common in keypad applications. The width of the filtered bounce is programmable. The module is capable of generating an interrupt request to the core once it identifies that any key has been pressed.

The interface supports a press-release-press mode and infra-structure for a press-hold mode. The former mode identifies a press, release and press of a key as two consecutive presses of the same key, whereas the latter mode checks the input key's state in periodic intervals to determine the number of times the same

key is meant to be pressed. It is possible to detect when multiple keys are pressed simultaneously and to provide limited key resolution capability when this happens.

SECURE DIGITAL (SD)/SDIO CONTROLLER

The SD/SDIO controller is a serial interface that stores data at a data rate of up to 10M bytes per second using a 4-bit data line.

The SD/SDIO controller supports the SD memory mode only. The interface supports all the power modes and performs error checking by CRC.

CODE SECURITY

An OTP/security system, consisting of a blend of hardware and software, provides customers with a flexible and rich set of code security features with Lockbox® secure technology. Key features include:

- OTP memory
- Unique chip ID
- Code authentication
- Secure mode of operation

The security scheme is based upon the concept of authentication of digital signatures using standards-based algorithms and provides a secure processing environment in which to execute code and protect assets. See [Lockbox Secure Technology Disclaimer on Page 23](#).

MEDIA TRANSCIEVER MAC LAYER (MXVR)

The ADSP-BF549 Blackfin processors provide a media transceiver (MXVR) MAC layer, allowing the processor to be connected directly to a MOST®¹ network through an FOT. See [Figure 5 on Page 15](#) for an example of a MXVR MOST connection.

The MXVR is fully compatible with industry-standard standalone MOST controller devices, supporting 22.579 Mbps or 24.576 Mbps data transfer. It offers faster lock times, greater jitter immunity, and a sophisticated DMA scheme for data transfers. The high speed internal interface to the core and L1 memory allows the full bandwidth of the network to be utilized. The MXVR can operate as either the network master or as a network slave.

The MXVR supports synchronous data, asynchronous packets, and control messages using dedicated DMA channels that operate autonomously from the processor core moving data to and from L1 and/or L2 memory. Synchronous data is transferred to or from the synchronous data physical channels on the MOST bus through eight programmable DMA channels. The synchronous data DMA channels can operate in various modes including modes that trigger DMA operation when data patterns are detected in the receive data stream. Furthermore, two DMA channels support asynchronous traffic, and two others support control message traffic.

¹ MOST is a registered trademark of Standard Microsystems, Corp.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Interrupts are generated when a user-defined amount of synchronous data has been sent or received by the processor or when asynchronous packets or control messages have been sent or received.

The MXVR peripheral can wake up the ADSP-BF549 Blackfin processor from sleep mode when a wakeup preamble is received over the network or based on any other MXVR interrupt event. Additionally, detection of network activity by the MXVR can be used to wake up the ADSP-BF549 Blackfin processor from the hibernate state. These features allow the ADSP-BF549 processor

to operate in a low-power state when there is no network activity or when data is not currently being received or transmitted by the MXVR.

The MXVR clock is provided through a dedicated external crystal or crystal oscillator. The frequency of the external crystal or crystal oscillator can be 256 Fs, 384 Fs, 512 Fs, or 1024 Fs for Fs = 38 kHz, 44.1 kHz, or 48 kHz. If using a crystal to provide the MXVR clock, use a parallel-resonant, fundamental mode, microprocessor-grade crystal.

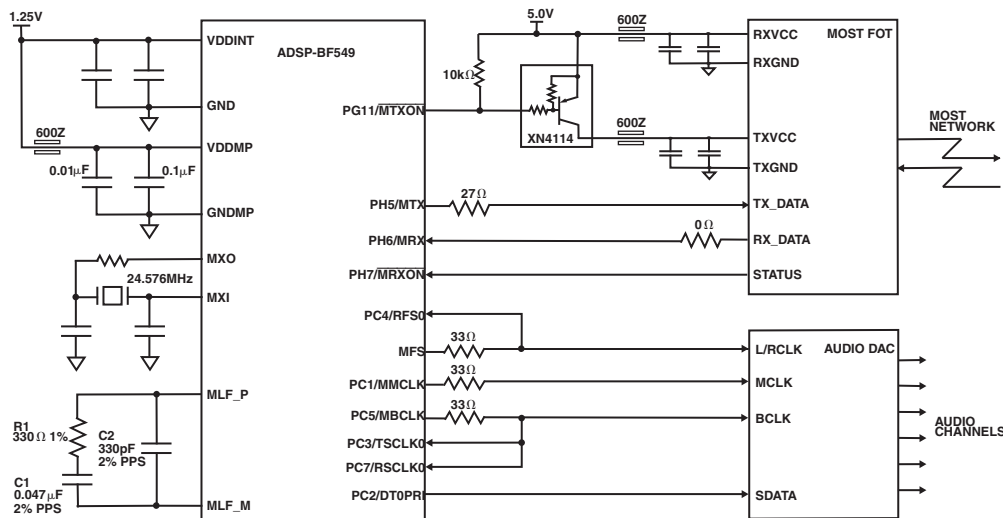

Figure 5. MXVR MOST Connection

DYNAMIC POWER MANAGEMENT

The ADSP-BF54x Blackfin processors provide five operating modes, each with a different performance/power profile. In addition, dynamic power management provides the control functions to dynamically alter the processor core supply voltage, further reducing power dissipation. Control of clocking to each of the ADSP-BF54x Blackfin processors' peripherals also reduces power consumption. See Table 4 for a summary of the power settings for each mode.

Full-On Operating Mode—Maximum Performance

In the full-on mode, the PLL is enabled and is not bypassed, providing the capability to run at the maximum operational frequency. This is the power-up default execution state in which maximum performance can be achieved. The processor core and all enabled peripherals run at full speed.

Active Operating Mode—Moderate Power Savings

In the active mode, the PLL is enabled but bypassed. Because the PLL is bypassed, the processor's core clock (CCLK) and system clock (SCLK) run at the input clock (CLKIN) frequency. DMA access is available to appropriately configured L1 memories.

In the active mode, it is possible to disable the control input to the PLL by setting the PLL_OFF bit in the PLL control register. This register can be accessed with a user-callable routine in the on-chip ROM called bfrom_SysControl(). For more information, see the "Dynamic Power Management" chapter in the ADSP-BF54x Blackfin Processor Hardware Reference. If disabled, the PLL must be re-enabled before transitioning to the full-on or sleep modes.

Table 4. Power Settings

Mode/State	PLL	PLL Bypassed	Core Clock (CCLK)	System Clock (SCLK)	Core Power
Full On	Enabled	No	Enabled	Enabled	On
Active	Enabled/Disabled	Yes	Enabled	Enabled	On
Sleep	Enabled	-	Disabled	Enabled	On
Deep Sleep	Disabled	-	Disabled	Disabled	On
Hibernate	Disabled	-	Disabled	Disabled	Off

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Sleep Operating Mode—High Dynamic Power Savings

The sleep mode reduces dynamic power dissipation by disabling the clock to the processor core (CCLK). The PLL and system clock (SCLK), however, continue to operate in this mode. Typically an external event or RTC activity will wake up the processor. In the sleep mode, assertion of a wakeup event enabled in the SIC_IWRx register causes the processor to sense the value of the BYPASS bit in the PLL control register (PLL_CTL). If BYPASS is disabled, the processor transitions to the full on mode. If BYPASS is enabled, the processor transitions to the active mode.

In the sleep mode, system DMA access to L1 memory is not supported.

Deep Sleep Operating Mode—Maximum Dynamic Power Savings

The deep sleep mode maximizes dynamic power savings by disabling the clocks to the processor core (CCLK) and to all synchronous peripherals (SCLK). Asynchronous peripherals, such as the RTC, may still be running but will not be able to access internal resources or external memory. This powered-down mode can only be exited by assertion of the reset interrupt ($\overline{\text{RESET}}$) or by an asynchronous interrupt generated by the RTC. In deep sleep mode, an asynchronous RTC interrupt causes the processor to transition to the active mode. Assertion of $\overline{\text{RESET}}$ while in deep sleep mode causes the processor to transition to the full on mode.

Hibernate State—Maximum Static Power Savings

The hibernate state maximizes static power savings by disabling the voltage and clocks to the processor core (CCLK) and to all the synchronous peripherals (SCLK). The internal voltage regulator for the processor can be shut off by using the `bfrom_SysControl()` function in the on-chip ROM. This sets the internal power supply voltage (V_{DDINT}) to 0 V to provide the greatest power savings mode. Any critical information stored internally (memory contents, register contents, and so on) must be written to a non-volatile storage device prior to removing power if the processor state is to be preserved.

Since V_{DDEXT} is still supplied in this mode, all of the external pins three-state, unless otherwise specified. This allows other devices that may be connected to the processor to have power still applied without drawing unwanted current.

The internal supply regulator can be woken up by CAN, by the MXVR, by the keypad, by the up/down counter, by the USB, and by some GPIO pins. It can also be woken up by a real-time clock wakeup event or by asserting the $\overline{\text{RESET}}$ pin. Waking up from hibernate state initiates the hardware reset sequence.

With the exception of the VR_CTL and the RTC registers, all internal registers and memories lose their content in hibernate state. State variables may be held in external SRAM or DDR memory.

Power Domains

As shown in Table 5, the ADSP-BF54x Blackfin processors support different power domains. The use of multiple power domains maximizes flexibility while maintaining compliance with industry standards and conventions. By isolating the internal logic of the ADSP-BF54x Blackfin processors into its own power domain separate from the RTC and other I/O, the processors can take advantage of dynamic power management without affecting the RTC or other I/O devices. There are no sequencing requirements for the various power domains.

Table 5. Power Domains

Power Domain	VDD Range
All internal logic, except RTC, DDR, and USB	V_{DDINT}
RTC internal logic and crystal I/O	V_{DDRTC}
DDR external memory supply	V_{DDDDR}
USB internal logic and crystal I/O	V_{DDUSB}
Internal voltage regulator	V_{DDVR}
MXVR PLL and logic	V_{DDMP}
All other I/O	V_{DDEXT}

VOLTAGE REGULATION

The ADSP-BF54x Blackfin processors provide an on-chip voltage regulator that can generate processor core voltage levels from an external supply (see specifications in [Operating Conditions on Page 34](#)). Figure 6 on Page 17 shows the typical external components required to complete the power management system. The regulator controls the internal logic voltage levels and is programmable with the voltage regulator control register (VR_CTL) in increments of 50 mV. This register can be accessed using the `bfrom_SysControl()` function in the on-chip ROM. To reduce standby power consumption, the internal voltage regulator can be programmed to remove power to the processor core while keeping I/O power supplied. While in hibernate state, V_{DDEXT} , V_{DDRTC} , V_{DDDDR} , V_{DDUSB} , and V_{DDVR} can still be applied, eliminating the need for external buffers. The voltage regulator can be activated from this power-down state by assertion of the $\overline{\text{RESET}}$ pin, which then initiates a boot sequence. The regulator can also be disabled and bypassed at the user's discretion. For all 600 MHz speed grade models and all automotive grade models, the internal voltage regulator must not be used and V_{DDVR} must be tied to V_{DDEXT} . For additional information regarding design of the voltage regulator circuit, see *Switching Regulator Design Considerations for the ADSP-BF533 Blackfin Processors (EE-228)*.

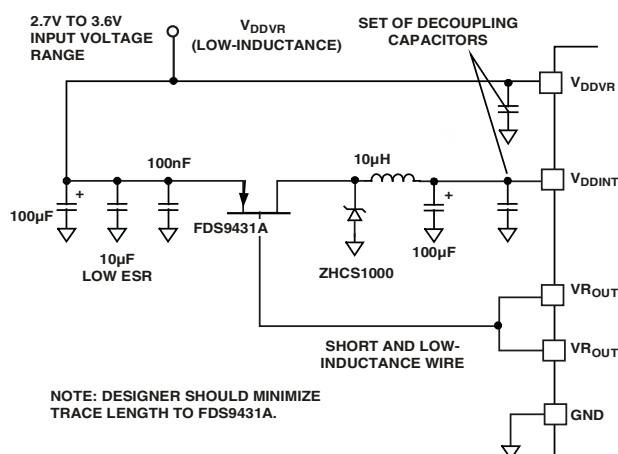

Figure 6. Voltage Regulator Circuit

CLOCK SIGNALS

The ADSP-BF54x Blackfin processors can be clocked by an external crystal, a sine wave input, or a buffered, shaped clock derived from an external clock oscillator.

If an external clock is used, it should be a TTL-compatible signal and must not be halted, changed, or operated below the specified frequency during normal operation. This signal is connected to the processor's CLKIN pin. When an external clock is used, the XTAL pin must be left unconnected.

Alternatively, because the ADSP-BF54x Blackfin processors include an on-chip oscillator circuit, an external crystal may be used. For fundamental frequency operation, use the circuit shown in Figure 7. A parallel-resonant, fundamental frequency, microprocessor-grade crystal is connected across the CLKIN and XTAL pins. The on-chip resistance between CLKIN and the XTAL pin is in the 500 kΩ range. Typically, further parallel resistors are not recommended. The two capacitors and the series resistor shown in Figure 7 fine-tune phase and amplitude of the sine frequency. The 1MΩ pull-up resistor on the XTAL pin guarantees that the clock circuit is properly held inactive when the processor is in the hibernate state.

The capacitor and resistor values shown in Figure 7 are typical values only. The capacitor values are dependent upon the crystal manufacturers' load capacitance recommendations and the PCB physical layout. The resistor value depends on the drive level specified by the crystal manufacturer. System designs should verify the customized values based on careful investigations on multiple devices over temperature range.

A third-overtone crystal can be used at frequencies above 25 MHz. The circuit is then modified to ensure crystal operation only at the third overtone by adding a tuned inductor circuit as shown in Figure 7. A design procedure for third-overtone operation is discussed in detail in an Application Note, *Using Third Overtone Crystals (EE-168)*.

The Blackfin core runs at a different clock rate than the on-chip peripherals. As shown in Figure 8 on Page 17, the core clock (CCLK) and system peripheral clock (SCLK) are derived from

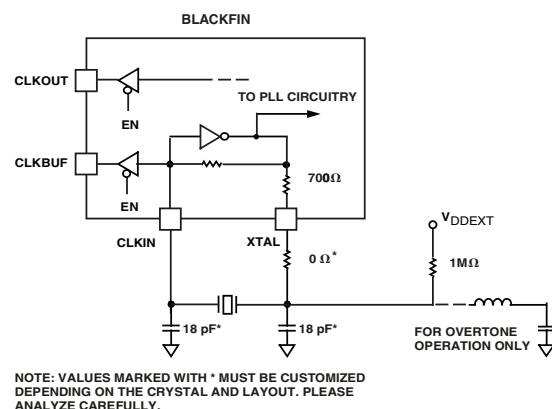

Figure 7. External Crystal Connections

the input clock (CLKIN) signal. An on-chip PLL is capable of multiplying the CLKIN signal by a programmable 0.5x to 64x multiplication factor (bounded by specified minimum and maximum VCO frequencies). The default multiplier is 8x, but it can be modified by a software instruction sequence. This sequence is managed by the `bfrom_SysControl()` function in the on-chip ROM.

On-the-fly CCLK and SCLK frequency changes can be applied by using the `bfrom_SysControl()` function in the on-chip ROM. Whereas the maximum allowed CCLK and SCLK rates depend on the applied voltages V_{DDINT} and V_{DDEXT} , the VCO is always permitted to run up to the frequency specified by the part's speed grade.

The CLKOUT pin reflects the SCLK frequency to the off-chip world. It functions as a reference for many timing specifications. While inactive by default, it can be enabled using the `EBIU_AMGCTL` register.

Note: For CCLK and SCLK specifications, see Table 15.

Figure 8. Frequency Modification Methods

All on-chip peripherals are clocked by the system clock (SCLK). The system clock frequency is programmable by means of the SSEL3-0 bits of the PLL_DIV register. The values programmed into the SSEL fields define a divide ratio between the PLL output (VCO) and the system clock. SCLK divider values are 1 through 15. Table 6 illustrates typical system clock ratios. The default ratio is 4.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Table 6. Example System Clock Ratios

Signal Name SSEL3-0	Divider Ratio VCO/SCLK	Example Frequency Ratios (MHz)	
		VCO	SCLK
0010	2:1	200	100
0110	6:1	300	50
1010	10:1	500	50

Note that the divisor ratio must be chosen to limit the system clock frequency to its maximum of f_{SCLK} . The SSEL value can be dynamically changed without any PLL lock latencies by writing the appropriate values to the PLL divisor register (PLL_DIV) using the `bfrom_SysControl()` function in the on-chip ROM.

The core clock (CCLK) frequency can also be dynamically changed by means of the CSEL1-0 bits of the PLL_DIV register. Supported CCLK divider ratios are 1, 2, 4, and 8, as shown in Table 7. The default ratio is 1. This programmable core clock capability is useful for fast core frequency modifications.

The maximum CCLK frequency not only depends on the part's speed grade, it also depends on the applied V_{DDINT} voltage. See Table 12 on Page 35 for details.

Table 7. Core Clock Ratios

Signal Name CSEL1-0	Divider Ratio VCO/CCLK	Example Frequency Ratios (MHz)	
		VCO	CCLK
00	1:1	300	300
01	2:1	300	150
10	4:1	500	125
11	8:1	200	25

BOOTING MODES

The ADSP-BF54x Blackfin processors have many mechanisms (listed in Table 8) for automatically loading internal and external memory after a reset. The boot mode is specified by four BMODE input pins dedicated to this purpose. There are two categories of boot modes: master and slave. In master boot modes, the processor actively loads data from parallel or serial memories. In slave boot modes, the processor receives data from an external host device.

Table 8. Booting Modes

BMODE3-0	Description
0000	Idle-no boot
0001	Boot from 8- or 16-bit external flash memory
0010	Boot from 16-bit asynchronous FIFO
0011	Boot from serial SPI memory (EEPROM or flash)
0100	Boot from SPI host device
0101	Boot from serial TWI memory (EEPROM or flash)
0110	Boot from TWI host
0111	Boot from UART host

Table 8. Booting Modes (Continued)

BMODE3-0	Description
1000	Reserved
1001	Reserved
1010	Boot from DDR SDRAM/Mobile DDR SDRAM
1011	Boot from OTP memory
1100	Reserved
1101	Boot from 8- or 16-bit NAND flash memory via NFC
1110	Boot from 16-bit host DMA
1111	Boot from 8-bit host DMA

The boot modes listed in Table 8 provide a number of mechanisms for automatically loading the processor's internal and external memories after a reset. By default, all boot modes use the slowest allowed configuration settings. Default settings can be altered via the initialization code feature at boot time or by proper OTP programming at pre-boot time. Some boot modes require a boot host wait (HWAIT) signal, which is a GPIO output signal that is driven and toggled by the boot kernel at boot time. If pulled high through an external pull-up resistor, the HWAIT signal behaves active high and will be driven low when the processor is ready for data. Conversely, when pulled low, HWAIT is driven high when the processor is ready for data. When the boot sequence completes, the HWAIT pin can be used for other purposes. By default, HWAIT functionality is on GPIO port B (PB11). However, if PB11 is otherwise utilized in the system, an alternate boot host wait (HWAITA) signal can be enabled on GPIO port H (PH7) by programming the `OTP_ALTERNATE_HWAIT` bit in the `PBS00L` OTP memory page.

The BMODE pins of the reset configuration register, sampled during power-on resets and software-initiated resets, implement the following modes:

- Idle-no boot mode (BMODE = 0x0)—In this mode, the processor goes into the idle state. The idle boot mode helps to recover from illegal operating modes, in case the OTP memory is misconfigured.
- Boot from 8- or 16-bit external flash memory—(BMODE = 0x1)—In this mode, the boot kernel loads the first block header from address 0x2000 0000 and, depending on instructions contained in the header, the boot kernel performs an 8- or 16-bit boot or starts program execution at the address provided by the header. By default, all configuration settings are set for the slowest device possible (3-cycle hold time; 15-cycle R/W access times; 4-cycle setup).

The ARDY pin is not enabled by default. It can, however, be enabled by OTP programming. Similarly, all interface behavior and timings can be customized through OTP programming. This includes activation of burst-mode or page-mode operation. In this mode, all asynchronous interface signals are enabled at the port muxing level.

- Boot from 16-bit asynchronous FIFO (BMODE = 0x2)—In this mode, the boot kernel starts booting from address 0x2030 0000. Every 16-bit word that the boot kernel has to read from the FIFO must be requested by a low pulse on the DMAR1 pin.
- Boot from serial SPI memory, EEPROM or flash (BMODE = 0x3)—8-, 16-, 24- or 32-bit addressable devices are supported. The processor uses the PE4 GPIO pin to select a single SPI EEPROM or flash device and uses SPI0 to submit a read command and successive address bytes (0x00) until a valid 8-, 16-, 24-, or 32-bit addressable device is detected. Pull-up resistors are required on the SPI0SEL1 and SPI0MISO pins. By default, a value of 0x85 is written to the SPI0_BAUD register.
- Boot from SPI host device (BMODE = 0x4)—The processor operates in SPI slave mode (using SPI0) and is configured to receive the bytes of the .LDR file from an SPI host (master) agent. The HWAIT signal must be interrogated by the host before every transmitted byte. A pull-up resistor is required on the SPI0SS input. A pull-down resistor on the serial clock (SPI0SCK) may improve signal quality and booting robustness.
- Boot from serial TWI memory, EEPROM or flash (BMODE = 0x5)—The processor operates in master mode (using TWI0) and selects the TWI slave with the unique ID 0xA0. The processor submits successive read commands to the memory device starting at two-byte internal address 0x0000 and begins clocking data into the processor. The TWI memory device should comply with Philips I²C Bus Specification version 2.1 and have the capability to auto-increment its internal address counter such that the contents of the memory device can be read sequentially. By default, a prescale value of 0xA and CLKDIV value of 0x0811 is used. Unless altered by OTP settings, an I²C memory that takes two address bytes is assumed. Development tools ensure that data that is booted to memories that cannot be accessed by the Blackfin core is written to an intermediate storage place and then copied to the final destination via memory DMA.
- Boot from TWI host (BMODE = 0x6)—The TWI host agent selects the slave with the unique ID 0x5F. The processor (using TWI0) replies with an acknowledgement, and the host can then download the boot stream. The TWI host agent should comply with Philips I²C Bus Specification version 2.1. An I²C multiplexer can be used to select one processor at a time when booting multiple processors from a single TWI.
- Boot from UART host (BMODE = 0x7)—In this mode, the processor uses UART1 as the booting source. Using an autobaud handshake sequence, a boot-stream-formatted program is downloaded by the host. The host agent selects a bit rate within the UART's clocking capabilities.

When performing the autobaud, the UART expects an "@" (0x40) character (eight data bits, one start bit, one stop bit, no parity bit) on the UART1RX pin to determine the bit rate. It then replies with an acknowledgement, which is

composed of four bytes (0xBF, the value of UART1_DLL, the value of UART1_DLH, and finally 0x00). The host can then download the boot stream. The processor deasserts the UART1RTS output to hold off the host; UART1CTS functionality is not enabled at boot time.

- Boot from (DDR) SDRAM (BMODE = 0xA)—In this mode, the boot kernel starts booting from address 0x0000 0010. This is a warm boot scenario only. The SDRAM is expected to contain a valid boot stream and the SDRAM controller must have been configured by the OTP settings.
- Boot from 8-bit and 16-bit external NAND flash memory (BMODE = 0xD)—In this mode, auto detection of the NAND flash device is performed. The processor configures PORTJ GPIO pins PJ1 and PJ2 to enable the ND_CE and ND_RB signals, respectively. For correct device operation, pull-up resistors are required on both ND_CE (PJ1) and ND_RB (PJ2) signals. By default, a value of 0x0033 is written to the NFC_CTL register. The booting procedure always starts by booting from byte 0 of block 0 of the NAND flash device. In this boot mode, the HWAIT signal does not toggle. The respective GPIO pin remains in the high-impedance state.

NAND flash boot supports the following features:

- Device auto detection
- Error detection and correction for maximum reliability
- No boot stream size limitation
- Peripheral DMA via channel 22, providing efficient transfer of all data (excluding the ECC parity data)
- Software-configurable boot mode for booting from boot streams expanding multiple blocks, including bad blocks
- Software-configurable boot mode for booting from multiple copies of the boot stream allowing for handling of bad blocks and uncorrectable errors
- Configurable timing via OTP memory

Small page NAND flash devices must have a 512-byte page size, 32 pages per block, a 16-byte spare area size and a bus configuration of eight bits. By default, all read requests from the NAND flash are followed by four address cycles. If the NAND flash device requires only three address cycles, then the device must be capable of ignoring the additional address cycle.

The small page NAND flash device must comply with the following command set:

Reset: 0xFF
Read lower half of page: 0x00
Read upper half of page: 0x01
Read spare area: 0x50

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

For large page NAND flash devices, the 4-byte electronic signature is read in order to configure the kernel for booting. This allows support for multiple large page devices. The fourth byte of the electronic signature must comply with the specifications in [Table 9](#).

Any configuration from [Table 9](#) that also complies with the command set listed below is directly supported by the boot kernel. There are no restrictions on the page size or block size as imposed by the small-page boot kernel.

Table 9. Byte 4 Electronic Signature Specification

Page Size (excluding spare area)	D1:D0	00	1K bytes
		01	2K bytes
		10	4K bytes
		11	8K bytes
Spare Area Size	D2	0	8 bytes/512 bytes
		1	16 bytes/512 bytes
Block Size (excluding spare area)	D5:4	00	64K bytes
		01	128K bytes
		10	256K bytes
		11	512K bytes
Bus Width	D6	0	x8
		1	x16
Not Used for Configuration	D3, D7		

Large page devices must support the following command set:

Reset: 0xFF
Read Electronic Signature: 0x90
Read: 0x00, 0x30 (confirm command)

Large page devices must not support or react to NAND flash command 0x50. This is a small page NAND flash command used for device auto detection.

By default, the boot kernel will always issue five address cycles; therefore, if a large page device requires only four cycles, the device must be capable of ignoring the additional address cycle.

16-bit NAND flash memory devices must only support the issuing of command and address cycles via the lower eight bits of the data bus. Devices that use the full 16-bit bus for command and address cycles are not supported.

- Boot from OTP memory (BMODE = 0xB)—This provides a standalone booting method. The boot stream is loaded from on-chip OTP memory. By default, the boot stream is expected to start from OTP page 0x40 and can occupy all

public OTP memory up to page 0xDF (2560 bytes). Since the start page is programmable, the maximum size of the boot stream can be extended to 3072 bytes.

- Boot from 16-bit host DMA (BMODE = 0xE)—In this mode, the host DMA port is configured in 16-bit acknowledge mode with little endian data format. Unlike other modes, the host is responsible for interpreting the boot stream. It writes data blocks individually into the host DMA port. Before configuring the DMA settings for each block, the host may either poll the ALLOW_CONFIG bit in HOST_STATUS or wait to be interrupted by the HWAIT signal. When using HWAIT, the host must still check ALLOW_CONFIG at least once before beginning to configure the host DMA port. After completing the configuration, the host is required to poll the READY bit in HOST_STATUS before beginning to transfer data. When the host sends an HIRQ control command, the boot kernel issues a CALL instruction to address 0xFFA0 0000. It is the host's responsibility to ensure valid code has been placed at this address. The routine at address 0xFFA0 0000 can be a simple initialization routine to configure internal resources, such as the SDRAM controller, which then returns using an RTS instruction. The routine may also be the final application, which will never return to the boot kernel.
- Boot from 8-bit host DMA (BMODE = 0xF)—In this mode, the host DMA port is configured in 8-bit interrupt mode with little endian data format. Unlike other modes, the host is responsible for interpreting the boot stream. It writes data blocks individually to the host DMA port. Before configuring the DMA settings for each block, the host may either poll the ALLOW_CONFIG bit in HOST_STATUS or wait to be interrupted by the HWAIT signal. When using HWAIT, the host must still check ALLOW_CONFIG at least once before beginning to configure the host DMA port. The host will receive an interrupt from the HOST_ACK signal every time it is allowed to send the next FIFO depth's worth (sixteen 32-bit words) of information. When the host sends an HIRQ control command, the boot kernel issues a CALL instruction to address 0xFFA0 0000. It is the host's responsibility to ensure valid code has been placed at this address. The routine at address 0xFFA0 0000 can be a simple initialization routine to configure internal resources, such as the SDRAM controller, which then returns using an RTS instruction. The routine may also be the final application, which will never return to the boot kernel.

For each of the boot modes, a 16-byte header is first read from an external memory device. The header specifies the number of bytes to be transferred and the memory destination address. Multiple memory blocks may be loaded by any boot sequence. Once all blocks are loaded, program execution commences from the address stored in the EVT1 register.

Prior to booting, the pre-boot routine interrogates the OTP memory. Individual boot modes can be customized or disabled based on OTP programming. External hardware, especially booting hosts, may monitor the HWAIT signal to determine

when the pre-boot has finished and the boot kernel starts the boot process. However, the HWAIT signal does not toggle in NAND boot mode. By programming OTP memory, the user can instruct the preboot routine to also customize the PLL, voltage regulator, DDR controller, and/or asynchronous memory interface controller.

The boot kernel differentiates between a regular hardware reset and a wakeup-from-hibernate event to speed up booting in the later case. Bits 6-4 in the system reset configuration (SYSCR) register can be used to bypass the pre-boot routine and/or boot kernel in case of a software reset. They can also be used to simulate a wakeup-from-hibernate boot in the software reset case.

The boot process can be further customized by “initialization code.” This is a piece of code that is loaded and executed prior to the regular application boot. Typically, this is used to configure the DDR controller or to speed up booting by managing PLL, clock frequencies, wait states, and/or serial bit rates.

The boot ROM also features C-callable function entries that can be called by the user application at run time. This enables second-stage boot or booting management schemes to be implemented with ease.

INSTRUCTION SET DESCRIPTION

The Blackfin processor family assembly language instruction set employs an algebraic syntax designed for ease of coding and readability. The instructions have been specifically tuned to provide a flexible, densely encoded instruction set that compiles to a very small final memory size. The instruction set also provides fully featured multifunction instructions that allow the programmer to use many of the processor core resources in a single instruction. Coupled with many features more often seen on microcontrollers, this instruction set is very efficient when compiling C and C++ source code. In addition, the architecture supports both user (algorithm/application code) and supervisor (O/S kernel, device drivers, debuggers, ISRs) modes of operation, allowing multiple levels of access to core processor resources.

The assembly language, which takes advantage of the processor's unique architecture, offers the following advantages:

- Seamlessly integrated DSP/MCU features are optimized for both 8-bit and 16-bit operations.
- A multi-issue load/store modified-Harvard architecture, which supports two 16-bit MAC or four 8-bit ALU + two load/store + two pointer updates per cycle.
- All registers, I/O, and memory are mapped into a unified 4G byte memory space, providing a simplified programming model.
- Microcontroller features, such as arbitrary bit and bit-field manipulation, insertion, and extraction; integer operations on 8-, 16-, and 32-bit data-types; and separate user and supervisor stack pointers.
- Code density enhancements, which include intermixing of 16- and 32-bit instructions (no mode switching, no code segregation). Frequently used instructions are encoded in 16 bits.

DEVELOPMENT TOOLS

Analog Devices supports its processors with a complete line of software and hardware development tools, including integrated development environments (which include CrossCore® Embedded Studio and/or VisualDSP++®), evaluation products, emulators, and a wide variety of software add-ins.

Integrated Development Environments (IDEs)

For C/C++ software writing and editing, code generation, and debug support, Analog Devices offers two IDEs.

The newest IDE, CrossCore Embedded Studio, is based on the Eclipse™ framework. Supporting most Analog Devices processor families, it is the IDE of choice for future processors, including multicore devices. CrossCore Embedded Studio seamlessly integrates available software add-ins to support real time operating systems, file systems, TCP/IP stacks, USB stacks, algorithmic software modules, and evaluation hardware board support packages. For more information visit www.analog.com/cces.

The other Analog Devices IDE, VisualDSP++, supports processor families introduced prior to the release of CrossCore Embedded Studio. This IDE includes the Analog Devices VDK real time operating system and an open source TCP/IP stack. For more information visit www.analog.com/visualdsp. Note that VisualDSP++ will not support future Analog Devices processors.

EZ-KIT Lite Evaluation Board

For processor evaluation, Analog Devices provides wide range of EZ-KIT Lite® evaluation boards. Including the processor and key peripherals, the evaluation board also supports on-chip emulation capabilities and other evaluation and development features. Also available are various EZ-Extenders®, which are daughter cards delivering additional specialized functionality, including audio and video processing. For more information visit www.analog.com and search on “ezkit” or “ezextender”.

EZ-KIT Lite Evaluation Kits

For a cost-effective way to learn more about developing with Analog Devices processors, Analog Devices offer a range of EZ-KIT Lite evaluation kits. Each evaluation kit includes an EZ-KIT Lite evaluation board, directions for downloading an evaluation version of the available IDE(s), a USB cable, and a power supply. The USB controller on the EZ-KIT Lite board connects to the USB port of the user's PC, enabling the chosen IDE evaluation suite to emulate the on-board processor in-circuit. This permits the customer to download, execute, and debug programs for the EZ-KIT Lite system. It also supports in-circuit programming of the on-board Flash device to store user-specific boot code, enabling standalone operation. With the full version of CrossCore Embedded Studio or VisualDSP++ installed (sold separately), engineers can develop software for supported EZ-KITs or any custom system utilizing supported Analog Devices processors.

Software Add-Ins for CrossCore Embedded Studio

Analog Devices offers software add-ins which seamlessly integrate with CrossCore Embedded Studio to extend its capabilities and reduce development time. Add-ins include board support packages for evaluation hardware, various middleware packages, and algorithmic modules. Documentation, help, configuration dialogs, and coding examples present in these add-ins are viewable through the CrossCore Embedded Studio IDE once the add-in is installed.

Board Support Packages for Evaluation Hardware

Software support for the EZ-KIT Lite evaluation boards and EZ-Extender daughter cards is provided by software add-ins called Board Support Packages (BSPs). The BSPs contain the required drivers, pertinent release notes, and select example code for the given evaluation hardware. A download link for a specific BSP is located on the web page for the associated EZ-KIT or EZ-Extender product. The link is found in the *Product Download* area of the product web page.

Middleware Packages

Analog Devices separately offers middleware add-ins such as real time operating systems, file systems, USB stacks, and TCP/IP stacks. For more information see the following web pages:

- www.analog.com/ucos3
- www.analog.com/ucfs
- www.analog.com/ucusbld
- www.analog.com/lwip

Algorithmic Modules

To speed development, Analog Devices offers add-ins that perform popular audio and video processing algorithms. These are available for use with both CrossCore Embedded Studio and VisualDSP++. For more information visit www.analog.com and search on “Blackfin software modules” or “SHARC software modules”.

Designing an Emulator-Compatible DSP Board (Target)

For embedded system test and debug, Analog Devices provides a family of emulators. On each JTAG DSP, Analog Devices supplies an IEEE 1149.1 JTAG Test Access Port (TAP). In-circuit emulation is facilitated by use of this JTAG interface. The emulator accesses the processor’s internal features via the processor’s TAP, allowing the developer to load code, set breakpoints, and view variables, memory, and registers. The processor must be halted to send data and commands, but once an operation is completed by the emulator, the DSP system is set to run at full speed with no impact on system timing. The emulators require the target board to include a header that supports connection of the DSP’s JTAG port to the emulator.

For details on target board design issues including mechanical layout, single processor connections, signal buffering, signal termination, and emulator pod logic, see the Engineer-to-Engineer Note “Analog Devices JTAG Emulation Technical Reference”

(EE-68) on the Analog Devices website (www.analog.com)—use site search on “EE-68.” This document is updated regularly to keep pace with improvements to emulator support.

MXVR BOARD LAYOUT GUIDELINES

The MXVR Loop Filter RC network is connected between the MLF_P and MLF_M pins in the following manner:

Capacitors:

- C1: 0.047 μ F (PPS type, 2% tolerance recommended)
- C2: 330 pF (PPS type, 2% tolerance recommended)

Resistor:

- R1: 330 Ω (1% tolerance)

The RC network should be located physically close to the MLF_P and MLF_M pins on the board.

The RC network should be shielded using GND_{MP} traces.

Avoid routing other switching signals near the RC network to avoid crosstalk.

MXI driven with external clock oscillator IC:

- MXI should be driven with the clock output of a clock oscillator IC running at a frequency of 49.152 MHz or 45.1584 MHz.
- MXO should be left unconnected.
- Avoid routing other switching signals near the oscillator and clock output trace to avoid crosstalk. When not possible, shield traces with ground.

MXI/MXO with external crystal:

- The crystal must be a fundamental mode crystal running at a frequency of 49.152 MHz or 45.1584 MHz.
- The crystal and load capacitors should be placed physically close to the MXI and MXO pins on the board.
- Board trace capacitance on each lead should not be more than 3 pF.
- Trace capacitance plus load capacitance should equal the load capacitance specification for the crystal.
- Avoid routing other switching signals near the crystal and components to avoid crosstalk. When not possible, shield traces and components with ground.

V_{DDMP}/GND_{MP}—MXVR PLL power domain:

- Route V_{DDMP} and GND_{MP} with wide traces or as isolated power planes.
- Drive V_{DDMP} to same level as V_{DDINT}.
- Place a ferrite bead between the V_{DDINT} power plane and the V_{DDMP} pin for noise isolation.
- Locally bypass V_{DDMP} with 0.1 μ F and 0.01 μ F decoupling capacitors to GND_{MP}.
- Avoid routing switching signals near to V_{DDMP} and GND_{MP} traces to avoid crosstalk.

Fiber optic transceiver (FOT) connections:

- Keep the traces between the ADSP-BF549 processor and the FOT as short as possible.
- The receive data trace connecting the FOT receive data output pin to the ADSP-BF549 PH6/MRX input pin should have a $0\ \Omega$ series termination resistor placed close to the FOT receive data output pin. Typically, the edge rate of the FOT receive data signal driven by the FOT is very slow, and further degradation of the edge rate is not desirable.
- The transmit data trace connecting the ADSP-BF549 PH5/MTX output pin to the FOT transmit data input pin should have a $27\ \Omega$ series termination resistor placed close to the ADSP-BF549 PH5/MTX pin.
- The receive data trace and the transmit data trace between the ADSP-BF549 processor and the FOT should not be routed close to each other in parallel over long distances to avoid crosstalk.

ADDITIONAL INFORMATION

The following publications that describe the ADSP-BF54x Blackfin processors (and related processors) can be ordered from any Analog Devices sales office or accessed electronically on www.analog.com:

- *ADSP-BF54x Blackfin Processor Hardware Reference, Volume 1 and Volume 2*
- *Blackfin Processor Programming Reference*
- *ADSP-BF542/BF544/BF547/BF548/BF549 Blackfin Anomaly List*

RELATED SIGNAL CHAINS

A *signal chain* is a series of signal-conditioning electronic components that receive input (data acquired from sampling either real-time phenomena or from stored data) in tandem, with the output of one portion of the chain supplying input to the next. Signal chains are often used in signal processing applications to gather and process data or to apply system controls based on analysis of real-time phenomena. For more information about this term and related topics, see the "signal chain" entry in [Wikipedia](http://en.wikipedia.org) or the [Glossary of EE Terms](#) on the Analog Devices website.

Analog Devices eases signal processing system development by providing signal processing components that are designed to work together well. A tool for viewing relationships between specific applications and related components is available on the www.analog.com website.

The Application Signal Chains page in the Circuits from the Lab™ site (<http://www.analog.com/circuits>) provides:

- Graphical circuit block diagram presentation of signal chains for a variety of circuit types and applications
- Drill down links for components in each chain to selection guides and application information
- Reference designs applying best practice design techniques

LOCKBOX SECURE TECHNOLOGY DISCLAIMER

Analog Devices products containing Lockbox Secure Technology are warranted by Analog Devices as detailed in the Analog Devices Standard Terms and Conditions of Sale. To our knowledge, the Lockbox secure technology, when used in accordance with the data sheet and hardware reference manual specifications, provides a secure method of implementing code and data safeguards. However, Analog Devices does not guarantee that this technology provides absolute security. ACCORDINGLY, ANALOG DEVICES HEREBY DISCLAIMS ANY AND ALL EXPRESS AND IMPLIED WARRANTIES THAT THE LOCKBOX SECURE TECHNOLOGY CANNOT BE BREACHED, COMPROMISED, OR OTHERWISE CIRCUMVENTED AND IN NO EVENT SHALL ANALOG DEVICES BE LIABLE FOR ANY LOSS, DAMAGE, DESTRUCTION, OR RELEASE OF DATA, INFORMATION, PHYSICAL PROPERTY, OR INTELLECTUAL PROPERTY.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

PIN DESCRIPTIONS

The ADSP-BF54x processor pin multiplexing scheme is shown in [Table 10](#).

Table 10. Pin Multiplexing

Primary Pin Function (Number of Pins) ^{1, 2}	First Peripheral Function	Second Peripheral Function	Third Peripheral Function	Fourth Peripheral Function	Interrupt Capability
Port A					
GPIO (16 pins)	SPORT2 (8 pins)	TMR4 (1 pin)	TACI7 (1 pin) TACLK7–0 (8 pins)		Interrupts (16 pins)
		TMR5 (1 pin)			
	SPORT3 (8 pins)	TMR6 (1 pin)			
		TMR7 (1 pin)			
Port B					
GPIO (15 pins)	TWI1 (2 pins) UART2 or 3 CTL (2 pins) UART2 (2 pins) UART3 (2 pins)		TACI2-3 (2 pins)		Interrupts (15 pins)
	SPI2 SEL1–3 (3 pins)	TMR0–2 (3 pins)	HWAIT (1 pin)		
	SPI2 (4 pins)	TMR3 (1 pin)			
Port C					
GPIO (16 pins)	SPORT0 (8 pins)	MXVR MMCLK, MBCLK (2 pins)			Interrupts (8 pins) ³
	SDH (6 pins)				Interrupts (8 pins)
Port D					
GPIO (16 pins)	PPI1 D0–15 (16 pins)	Host D0–15 (16 pins)	SPORT1 (8 pins)	PPIO D18– 23 (6 pins)	Interrupts (8 pins)
			PPI2 D0–7 (8 pins)	Keypad Row 0–3 Col 0–3 (8 pins)	Interrupts (8 pins)
Port E					
GPIO (16 pins)	SPI0 (7 pins)	Keypad Row 4–6 Col 4–7 (7 pins)	TACI0 (1 pin)		Interrupts (8 pins)
	UART0 TX (1 pin)	Keypad R7 (1 pin)			
	UART0 RX (1 pin) UART0 or 1 CTL (2 pins) PPI1 CLK,FS (3 pins) TWI0 (2 pins)				Interrupts (8 pins)
Port F					
GPIO (16 pins)	PPIO D0–15 (16 pins)	ATAPI D0-15A			Interrupts (8 pins) Interrupts (8 pins)
Port G					
GPIO (16 pins)	PPIO CLK,FS (3 pins) DATA 16–17 (2 pins)	TMRCLK (1 pin)			Interrupts (8 pins)
		ATAPI A0-2A			
	SPI1 SEL1–3 (3 pins)	Host CTL (3 pins)	PPI2 CLK,FS (3 pins)	CZM (1 pin)	
	SPI1 (4 pins)	MXVR MTXON (1 pin)	TACI4-5 (2 pins)		
	CAN0 (2 pins)				
	CAN1 (2 pins)				

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Table 10. Pin Multiplexing (Continued)

Primary Pin Function (Number of Pins) ^{1, 2}	First Peripheral Function	Second Peripheral Function	Third Peripheral Function	Fourth Peripheral Function	Interrupt Capability
Port H					
GPIO (14 pins)	UART1 (2 pins)	PPIO-1_FS3 (2 pins)	TAC11 (1 pin)		Interrupts (8 pins)
	ATAPI_RESET (1 pin)	TMR8 (1 pin)	PPI2_FS3 (1 pin)		
	HOST_ADDR (1 pin)	TMR9 (1 pin)	Counter Down/Gate (1 pin)		
	HOST_ACK (1 pin)	TMR10 (1 pin)	Counter Up/Dir (1 pin)		
	MXVR MRX, MTX, MRXON/GPW (3 pins) ⁴		DMAR 0–1 (2 pins)	TAC18–10 (3 pins) TACLK8–10 (3 pins) HWAITA	
		AMC Addr 4-9 (6 pins)			Interrupts (6 pins)
Port I					
GPIO (16 pins)	Async Addr10–25 (16 pins)				Interrupts (8 pins)
					Interrupts (8 pins)
Port J					
GPIO (14 pins)	Async CTL and MISC				Interrupts (8 pins)
					Interrupts (6 pins)

¹ Port connections may be inputs or outputs after power up depending on the model and boot mode chosen.

² All port connections always power up as inputs for some period of time and require resistive termination to a safe condition if used as outputs in the system.

³ A total of 32 interrupts at once are available from ports C through J, configurable in byte-wide blocks.

⁴ GPW functionality available when MXVR is not present or unused.

Pin definitions for the ADSP-BF54x processors are listed in [Table 11](#). In order to maintain maximum function and reduce package size and ball count, some balls have dual, multiplexed functions. In cases where ball function is reconfigurable, the default state is shown in plain text, while the alternate function is shown in italics.

All pins are three-stated during and immediately after reset, with the exception of the external memory interface, asynchronous and synchronous memory control, and the buffered XTAL output pin (CLKBUF). On the external memory interface, the control and address lines are driven high, with the exception of CLKOUT, which toggles at the system clock rate. During hibernate, all outputs are three-stated unless otherwise noted in [Table 11](#).

All I/O pins have their input buffers disabled with the exception of the pins that need pull-ups or pull-downs, as noted in [Table 11](#).

It is strongly advised to use the available IBIS models to ensure that a given board design meets overshoot/undershoot and signal integrity requirements.

Additionally, adding a parallel termination to CLKOUT may prove useful in further enhancing signal integrity. Be sure to verify overshoot/undershoot and signal integrity specifications on actual hardware.

Pin Name	I/O ¹	Function (First/Second/Third/Fourth)	Driver Type ²
USB_VBUS ¹¹	I/O	USB VBUS Pin (Pull high or low when unused.)	
USB_VREF	A	USB Voltage Reference (Connect to GND through a 0.1 μ F capacitor or leave unconnected when not used.)	
USB_RSET	A	USB Resistance Set (Connect to GND through an unpopulated resistor pad.)	
MXVR (MOST) Interface			
MFS	O	MXVR Frame Sync (Leave unconnected when unused.)	C
MLF_P	A	MXVR Loop Filter Plus (Leave unconnected when unused.)	
MLF_M	A	MXVR Loop Filter Minus (Leave unconnected when unused.)	
MXI	C	MXVR Crystal Input (Pull high or low when unused.)	
MXO	C	MXVR Crystal Output (Pull high or low when unused.)	
Mode Control Pins			
BMODE0–3	I	Boot Mode Strap 0–3	
JTAG Port Pins			
TDI	I	JTAG Serial Data In	
TDO	O	JTAG Serial Data Out	C
$\overline{\text{TRST}}$	I	JTAG Reset (Pull low when unused.)	
TMS	I	JTAG Mode Select	
TCK	I	JTAG Clock	
$\overline{\text{EMU}}$	O	Emulation Output	C
Voltage Regulator			
VR _{OUT0} , VR _{OUT1}	O	External FET/BJT Drivers (Always connect together to reduce signal impedance.)	
Real Time Clock			
RTXO	C	RTC Crystal Output (Leave unconnected when unused. Does not three-state during hibernate.)	
RTXI	C	RTC Crystal Input (Pull high or low when unused.)	
Clock (PLL) Pins			
CLKIN	C	Clock/Crystal Input	
CLKOUT	O	Clock Output	B
XTAL	C	Crystal Output (If CLKBUF is enabled, does not three-state during hibernate.)	
CLKBUF	O	Buffered Oscillator Output (If enabled, does not three-state during hibernate.)	C
EXT_WAKE	O	External Wakeup from Hibernate Output (Does not three-state during hibernate.)	A
$\overline{\text{RESET}}$	I	Reset	
$\overline{\text{NMI}}$	I	Non-maskable Interrupt (Pull high when unused.)	

Table 11. Pin Descriptions (Continued)

Pin Name	I/O ¹	Function (First/Second/Third/Fourth)	Driver Type ²
Supplies			
V _{DDINT}	P	Internal Power Supply	
V _{DDEXT} ¹²	P	External Power Supply	
V _{DDDDR} ¹²	P	External DDR Power Supply	
V _{DDUSB} ¹²	P	External USB Power Supply	
V _{DDRTC} ¹²	P	RTC Clock Supply	
V _{DDVR} ¹³	P	Internal Voltage Regulator Power Supply (Connect to V _{DDEXT} when unused.)	
GND	G	Ground	
V _{DDMP} ¹²	P	MXVR PLL Power Supply. (Must be driven to same level as V _{DDINT} . Connect to V _{DDINT} when unused or when MXVR is not present.)	
GND _{MP} ¹²	G	MXVR PLL Ground (Connect to GND when unused or when MXVR is not present.)	

¹ I = Input, O = Output, P = Power, G = Ground, C = Crystal, A = Analog.

² Refer to [Table 62 on Page 88](#) through [Table 71 on Page 89](#) for driver types.

³ To use the SPI memory boot, SPI0SCK should have a pulldown, SPI0MISO should have a pullup, and $\overline{\text{SPI0SEL1}}$ is used as the $\overline{\text{CS}}$ with a pullup.

⁴ HWAIT/HWAITA should be pulled high or low to configure polarity. See [Booting Modes on Page 18](#).

⁵ $\overline{\text{GPW}}$ functionality is available when MXVR is not present or unused.

⁶ This pin should not be used as GPIO if booting in mode 1.

⁷ This pin should always be enabled as $\overline{\text{ND_CE}}$ in software and pulled high with a resistor when using NAND flash.

⁸ This pin should always be enabled as $\overline{\text{BR}}$ in software and pulled high to enable asynchronous access.

⁹ This pin must be pulled low through a 10kOhm resistor if self-refresh mode is desired during hibernate state or deep-sleep mode.

¹⁰ If the USB is used in device mode only, the USB_ID pin should be either pulled high or left unconnected.

¹¹ This pin is an output only during initialization of USB OTG session request pulses in peripheral mode. Therefore, host mode or OTG type A mode requires that an external voltage source of 5 V, at 8 mA or more per the OTG specification, be applied to this pin. Other OTG modes require that this external voltage be disabled.

¹² To ensure proper operation, the power pins should be driven to their specified level even if the associated peripheral is not used in the application.

¹³ This pin must always be connected. If the internal voltage regulator is not being used, this pin may be connected to V_{DDEXT}. Otherwise it should be powered according to the VDDVR specification. For automotive grade models, the internal voltage regulator must not be used and this pin must be tied to V_{DDEXT}.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

SPECIFICATIONS

OPERATING CONDITIONS

Parameter	Conditions	Min	Nominal	Max	Unit
$V_{DDINT}^{1,2}$	Internal Supply Voltage	0.9		1.43	V

	Junction Temperature	400-Ball CSP_BGA @ $T_{AMBIENT} = -40^\circ\text{C}$ to $+105^\circ\text{C}$	-40	+125	°C

¹ See Table 12 on Page 35 for frequency/voltage specifications.

² V_{DDINT} maximum is 1.10 V during one-time-programmable (OTP) memory programming operations.

³ V_{DDEXT} minimum is 3.0 V and maximum is 3.6 V during OTP memory programming operations.

⁴ Use of the internal voltage regulator is not supported on 600 MHz speed grade models or on automotive grade models. An external voltage regulator must be used.

⁵ Bidirectional pins (D15-0, PA15-0, PB14-0, PC15-0, PD15-0, PE15-0, PF15-0, PG15-0, PH13-0, PI15-0, PJ14-0) and input pins (ATAPI_PDIAG, USB_ID, TCK, TDI, TMS, TRST, CLKIN, RESET, NMI, and BMODE3-0) of the ADSP-BF54x Blackfin processors are 3.3 V-tolerant (always accept up to 3.6 V maximum V_{IH}). Voltage compliance (on outputs, V_{OH}) is limited by the V_{DDEXT} supply voltage. The regulator can generate V_{DDINT} at levels of 0.90 V to 1.30 V with -5% to +5% tolerance.

⁶ Parameter value applies to all input and bidirectional pins except PB1-0, PE15-14, PG15-11, PH7-6, DQ0-15, and DQS0-1.

⁷ Parameter value applies to pins DQ0-15 and DQS0-1.

⁸ PB1-0, PE15-14, PG15-11, and PH7-6 are 5.0 V-tolerant (always accept up to 5.5 V maximum V_{IH} when power is applied to V_{DDEXT} pins). Voltage compliance (on output V_{OH}) is limited by V_{DDEXT} supply voltage.

⁹ SDA and SCL are 5.0 V tolerant (always accept up to 5.5 V maximum V_{IH}). Voltage compliance on outputs (V_{OH}) is limited by the V_{DDEXT} supply voltage.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

¹⁰Parameter value applies to USB_DP, USB_DM, and USB_VBUS pins. See [Absolute Maximum Ratings on Page 40](#).

¹¹Parameter value applies to all input and bidirectional pins, except PB1-0, PE15-14, PG15-11, and PH7-6.

¹²Parameter value applies to pins PG15-11 and PH7-6.

¹³Parameter value applies to pins PB1-0 and PE15-14. Consult the I²C specification version 2.1 for the proper resistor value and other open drain pin electrical parameters.

¹⁴T_J must be in the range: 0°C < T_J < 55°C during OTP memory programming operations.

Table 12 and Table 15 describe the voltage/frequency requirements for the ADSP-BF54x Blackfin processors' clocks. Take care in selecting MSEL, SSEL, and CSEL ratios so as not to exceed the maximum core clock and system clock. Table 14 describes the phase-locked loop operating conditions.

Table 12. Core Clock (CCLK) Requirements—533 MHz and 600 MHz Speed Grade¹

Parameter	Min V _{DDINT}	Internal Regulator Setting ²	Max CCLK Frequency	Unit
f _{CCLK} Core Clock Frequency	1.30 V	N/A ²	600	MHz
	1.188 V	1.25 V	533	MHz
	1.14 V	1.20 V	500	MHz
	1.045 V	1.10 V	444	MHz
	0.95 V	1.00 V	400	MHz
	0.90 V	0.95 V	333	MHz

¹ See the [Ordering Guide on Page 101](#).

² Use of an internal voltage regulator is not supported on automotive grade and 600 MHz speed grade models. Internal regulator setting should be used as recommended nominal V_{DDINT} for external regulator.

Table 13. Core Clock (CCLK) Requirements—400 MHz Speed Grade¹

Parameter	Min V _{DDINT}	Internal Regulator Setting ²	Max CCLK Frequency	Unit
f _{CCLK} Core Clock Frequency	1.14 V	1.20 V	400	MHz
	1.045 V	1.10 V	364	MHz
	0.95 V	1.00 V	333	MHz
	0.90 V	0.95 V	300	MHz

¹ See [Ordering Guide on Page 101](#).

² Use of an internal voltage regulator is not supported on automotive grade models. Internal regulator setting should be used as recommended nominal V_{DDINT} for external regulator.

Table 14. Phase-Locked Loop Operating Conditions

Parameter	Min	Max	Unit
f _{VCO} Voltage Controlled Oscillator (VCO) Frequency	50	Maximum f _{CCLK}	MHz

Table 15. System Clock Requirements

Parameter	Condition	DDR SDRAM Models	Mobile DDR SDRAM Models		Unit
		Max	Min	Max	
f _{SCLK}	V _{DDINT} ≥ 1.14 V ¹ , Non-extended temperature grades	133 ²	120 ³	133 ²	MHz
f _{SCLK}	V _{DDINT} < 1.14 V ¹ , Non-extended temperature grades	100	N/A ⁴	N/A ⁴	MHz
f _{SCLK}	V _{DDINT} ≥ 1.0 V ¹ , Extended temperature grade	100	N/A	N/A	MHz

¹ f_{SCLK} must be less than or equal to f_{CCLK}.

² Rounded number. Actual test specification is SCLK period of 7.5 ns. See [Table 25 on Page 43](#).

³ Rounded number. Actual test specification is SCLK period of 8.33 ns.

⁴ V_{DDINT} must be greater than or equal to 1.14 V for mobile DDR SDRAM models. See [Operating Conditions on Page 34](#).

¹ Applies to all nonautomotive 400 MHz speed grade models and all extended temperature grade models. See [Ordering Guide](#).

² Applies to all 533 MHz and 600 MHz speed grade models and automotive 400 MHz speed grade models. See [Ordering Guide](#).

³ Applies to output and bidirectional pins, except USB_VBUS and the pins listed in table note 4.

⁴ Applies to pins DA0–12, DBA0–1, DQ0–15, DQS0–1, DQM0–1, DCLK1–2, DCLK1–2, DCS0–1, DCLKE, DRAS, DCAS, and DWE.

⁵ Applies to all input pins except JTAG inputs.

⁶ Applies to JTAG input pins (TCK, TDI, TMS, TRST).

⁷ Applies to DDR_VREF pin.

⁸ Absolute value.

⁹ For DDR pins (DQ0–15, DQS0–1), test conditions are $V_{DDDDR} = \text{Maximum}$, $V_{IN} = V_{DDDDR} \text{ Maximum}$.

¹⁰ Applies to three-statable pins.

¹¹ For DDR pins (DQ0–15, DQS0–1), test conditions are $V_{DDDDR} = \text{Maximum}$, $V_{IN} = 0$ V.

¹² Guaranteed, but not tested.

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

¹³See the ADSP-BF54x Blackfin Processor Hardware Reference Manual for definition of sleep, deep sleep, and hibernate operating modes.

¹⁴Includes current on V_{DDEXT}, V_{DDUSB}, V_{DDVR}, and V_{DDDDR} supplies. Clock inputs are tied high or low.

¹⁵Guaranteed maximum specifications.

¹⁶Unit for V_{DDINT} is V (volts). Unit for f_{SCLK} is MHz. Example: 1.2 V, 133 MHz would be $0.77 \times 1.2 \times 133 = 122.9$ mA added to I_{DDDEEPSLEEP}.

¹⁷See Table 18 for the list of I_{DDINT} power vectors covered.

Total power dissipation has two components:

- Static, including leakage current
- Dynamic, due to transistor switching characteristics

Many operating conditions can also affect power dissipation, including temperature, voltage, operating frequency, and processor activity. [Electrical Characteristics on Page 36](#) shows the current dissipation for internal circuitry (V_{DDINT}). I_{DDDEEPSLEEP} specifies static power dissipation as a function of voltage (V_{DDINT}) and temperature (see [Table 16](#) and [Table 17](#)), and

I_{DDINT} specifies the total power specification for the listed test conditions, including the dynamic component as a function of voltage (V_{DDINT}) and frequency ([Table 19](#)).

There are two parts to the dynamic component. The first part is due to transistor switching in the core clock (CCLK) domain. This part is subject to an activity scaling factor (ASF) which represents application code running on the processor core and L1/L2 memories ([Table 18](#)). The ASF is combined with the CCLK frequency and V_{DDINT} dependent data in [Table 19](#) to calculate this part. The second part is due to transistor switching in the system clock (SCLK) domain, which is included in the I_{DDINT} specification equation.

Table 16. Static Current—Low Power Process (mA)¹

¹ The values are not guaranteed as stand-alone maximum specifications. They must be combined with static current per the equations of [Electrical Characteristics on Page 36](#).

² Valid frequency and voltage ranges are model-specific. See [Operating Conditions on Page 34](#).

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

ABSOLUTE MAXIMUM RATINGS

Stresses greater than those listed in Table 20 may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions greater than those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Table 21 details the maximum duty cycle for input transient voltage.

Table 20. Absolute Maximum Ratings

Internal (Core) Supply Voltage (V_{DDINT})	–0.3 V to +1.43 V
External (I/O) Supply Voltage (V_{DDEXT})	–0.3 V to +3.8 V
Input Voltage ^{1, 2, 3}	–0.5 V to +3.6 V
Output Voltage Swing	–0.5 V to $V_{DDEXT} + 0.5$ V
I_{OH}/I_{OL} Current per Single Pin ⁴	40 mA (max)
I_{OH}/I_{OL} Current per Pin Group ⁴	80 mA (max)
Storage Temperature Range	–65°C to +150°C
Junction Temperature Underbias	+125°C

¹ Applies to all bidirectional and input only pins except PB1-0, PE15-14, PG15-11, and PH7-6, where the absolute maximum input voltage range is –0.5 V to +5.5 V.

² Pins USB_DP, USB_DM, and USB_VBUS are 5 V-tolerant when VDDUSB is powered according to the operating conditions table. If VDDUSB supply voltage does not meet the specification in the operating conditions table, these pins could suffer long-term damage when driven to +5 V. If this condition is seen in the application, it can be corrected with additional circuitry to use the external host to power only the VDDUSB pins. Contact factory for application detail and reliability information.

³ Applies only when V_{DDEXT} is within specifications. When V_{DDEXT} is outside specifications, the range is $V_{DDEXT} \pm 0.2$ V.

⁴ For more information, see description preceding Table 22.

Table 21. Maximum Duty Cycle for Input¹ Transient Voltage

V_{IN} Max (V) ²	V_{IN} Min (V)	Maximum Duty Cycle
3.63	–0.33	100%
3.80	–0.50	48%
3.90	–0.60	30%
4.00	–0.70	20%
4.10	–0.80	10%
4.20	–0.90	8%
4.30	–1.00	5%

¹ Does not apply to CLKIN. Absolute maximum for pins PB1-0, PE15-14, PG15-11, and PH7-6 is +5.5V.

² Only one of the listed options can apply to a particular design.

The Absolute Maximum Ratings table specifies the maximum total source/sink (I_{OH}/I_{OL}) current for a group of pins. Permanent damage can occur if this value is exceeded. To understand this specification, if pins PA4, PA3, PA2, PA1 and PA0 from group 1 in the Total Current Pin Groups table were sourcing or sinking 2 mA each, the total current for those pins would be 10 mA. This would allow up to 70 mA total that could be sourced or sunk by the remaining pins in the group without damaging the device. For a list of all groups and their pins, see

the Total Current Pin Groups table. Note that the V_{OL} and V_{OH} specifications have separate per-pin maximum current requirements, see the Electrical Characteristics table.

Table 22. Total Current Pin Groups

Group	Pins in Group
1	PA0, PA1, PA2, PA3, PA4, PA5, PA6, PA7, PA8, PA9, PA10, PA11

ESD SENSITIVITY

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PACKAGE INFORMATION

The information presented in [Figure 9](#) and [Table 23](#) provides information related to specific product features. For a complete listing of product offerings, see the [Ordering Guide on Page 101](#).

yyww	Date Code

TIMING SPECIFICATIONS

Timing specifications are detailed in this section.

Clock and Reset Timing

Table 24 and Figure 10 describe Clock Input and Reset Timing.

Table 25 and Figure 11 describe Clock Out Timing.

Table 24. Clock Input and Reset Timing

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
t_{CKIN}	CLKIN Period ^{1, 2, 3, 4}	20.0	100.0	ns
t_{CKINL}	CLKIN Low Pulse ²	8.0		ns
t_{CKINH}	CLKIN High Pulse ²	8.0		ns
$t_{BUFDLAY}$	CLKIN to CLKBUF Delay		10	ns
t_{WRST}	\overline{RESET} Asserted Pulsewidth Low ⁵	11 t_{CKIN}		ns
t_{RHWFT}	RESET High to First HWAIT/HWAITA Transition (Boot Host Wait Mode) ^{6, 7, 8, 9}	6100 t_{CKIN} + 7900 t_{SCLK}		ns
	RESET High to First HWAIT/HWAITA Transition (Reset Output Mode) ^{7, 10, 11}	6100 t_{CKIN}	7000 t_{CKIN}	ns

¹ Combinations of the CLKIN frequency and the PLL clock multiplier must not exceed the allowed f_{VCO} , f_{CCLK} , and f_{SCLK} settings discussed in Table 15 and Table 12 on Page 35.

² Applies to PLL bypass mode and PLL non-bypass mode.

³ CLKIN frequency and duty cycle must not change on the fly.

⁴ If the DF bit in the PLL_CTL register is set, then the maximum t_{CKIN} period is 50 ns.

⁵ Applies after power-up sequence is complete. See Table 26 and Figure 12 for more information about power-up reset timing.

⁶ Maximum value not specified due to variation resulting from boot mode selection and OTP memory programming.

⁷ Values specified assume no invalidation preboot settings in OTP page PBS00L. Invalidating a PBS set will increase the value by 1875 t_{CKIN} (typically).

⁸ Applies only to boot modes BMODE=1, 2, 4, 6, 7, 10, 11, 14, 15.

⁹ Use default t_{SCLK} value unless PLL is reprogrammed during preboot. In case of PLL reprogramming use the new t_{SCLK} value and add PLL_LOCKCNT settle time.

¹⁰ When enabled by OTP_RESETOUT_HWAIT bit. If regular HWAIT is not required in an application, the OTP_RESETOUT_HWAIT bit in the same page instructs the HWAIT or HWAITA to simulate reset output functionality. Then an external resistor is expected to pull the signal to the reset level, as the pin itself is in high performance mode during reset.

¹¹ Variances are mainly dominated by PLL programming instructions in PBS00L page and boot code differences between silicon revisions. The earlier is bypassed in boot mode BMODE = 0. Maximum value assumes PLL programming instructions do not cause the SCLK frequency to decrease.

Figure 10. Clock and Reset Timing

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Table 25. Clock Out Timing

Parameter		Min	Max	Unit
<i>Switching Characteristics</i>				
t_{SCLK}	CLKOUT Period ^{1,2}	7.5		ns
t_{SCLKH}	CLKOUT Width High	2.5		ns
t_{SCLKL}	CLKOUT Width Low	2.5		ns

¹ The t_{SCLK} value is the inverse of the f_{SCLK} specification. Reduced supply voltages affect the best-case value of 7.5 ns listed here.

² The t_{SCLK} value does not account for the effects of jitter.

Figure 11. CLKOUT Interface Timing

Table 26. Power-Up Reset Timing

Parameter		Min	Max	Unit
<i>Timing Requirement</i>				
$t_{RST_IN_PWR}$	\overline{RESET} Deasserted After the V_{DDINT} , V_{DDEXT} , V_{DDDDR} , V_{DDUSB} , V_{DDRTC} , V_{DDVR} , V_{DDMP} , and CLKIN Pins Are Stable and Within Specification	$3500 \times t_{CKIN}$		ns

In Figure 12, $V_{DD_SUPPLIES}$ is V_{DDINT} , V_{DDEXT} , V_{DDDDR} , V_{DDUSB} , V_{DDRTC} , V_{DDVR} , and V_{DDMP} .

Parameter	Min	Max	Unit
<i>Timing Requirement</i>			
t_{WBR} $\overline{\text{BR}}$ Pulsewidth	$2 \times t_{\text{SCLK}}$		ns
<i>Switching Characteristics</i>			
t_{SD} CLKOUT Low to $\overline{\text{AMSx}}$, Address, and $\overline{\text{ARE}}/\overline{\text{AWE}}$ Disable		5.0	ns
t_{SE} CLKOUT Low to $\overline{\text{AMSx}}$, Address, and $\overline{\text{ARE}}/\overline{\text{AWE}}$ Enable		5.0	ns
t_{DBG} CLKOUT Low to $\overline{\text{BG}}$ Asserted Output Delay		4.0	ns
t_{EBG} CLKOUT Low to $\overline{\text{BG}}$ Deasserted Output Hold		4.0	ns
t_{DBH} CLKOUT Low to $\overline{\text{BGH}}$ Asserted Output Delay		3.6	ns
t_{EBH} CLKOUT Low to $\overline{\text{BGH}}$ Deasserted Output Hold		3.6	ns

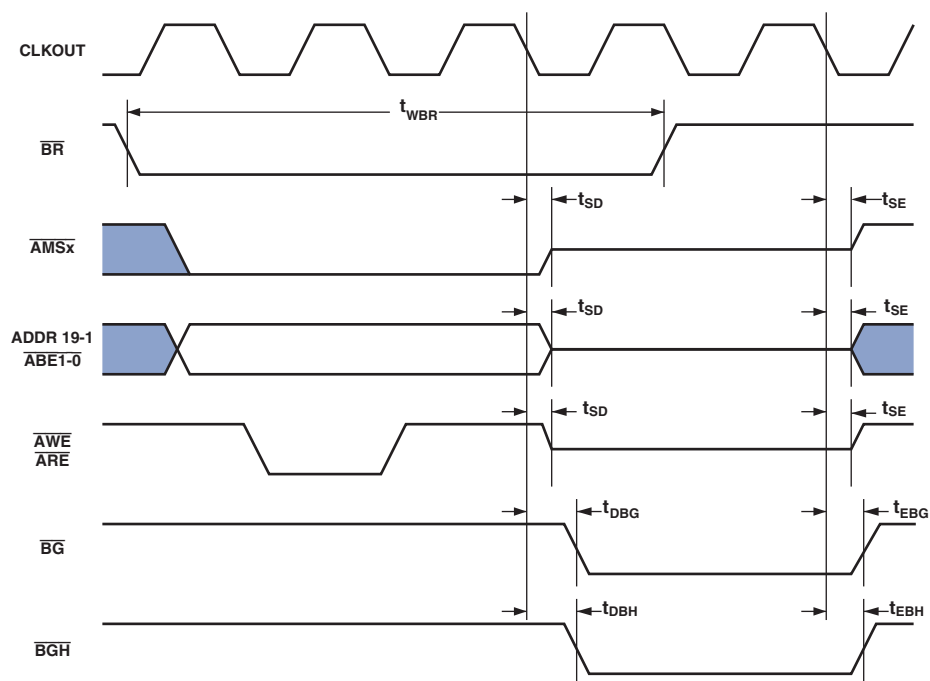

Figure 22. External Port Bus Request and Grant Cycle Timing with Asynchronous $\overline{\text{BR}}$

NAND Flash Controller Interface Timing

Table 36 and Figure 23 on Page 54 through Figure 27 on Page 56 describe NAND flash controller interface operations. In the figures, ND_DATA is ND_D0–D15.

Table 36. NAND Flash Controller Interface Timing

Parameter	Min	Max	Unit
Write Cycle			
<i>Switching Characteristics</i>			
t_{CWL} ND_CE Setup Time to \overline{AWE} Low	$1.0 \times t_{SCLK} - 4$		ns
t_{CH} ND_CE Hold Time from \overline{AWE} High	$3.0 \times t_{SCLK} - 4$		ns
t_{CLEWL} ND_CLE Setup Time High to \overline{AWE} Low	0.0		ns
t_{CLH} ND_CLE Hold Time from \overline{AWE} High	$2.5 \times t_{SCLK} - 4$		ns
t_{ALEWL} ND_ALE Setup Time Low to \overline{AWE} Low	0.0		ns
t_{ALH} ND_ALE Hold Time from \overline{AWE} High	$2.5 \times t_{SCLK} - 4$		ns
t_{WP}^1 \overline{AWE} Low to \overline{AWE} High	$(WR_DLY + 1.0) \times t_{SCLK} - 4$		ns
t_{WHWL} \overline{AWE} High to \overline{AWE} Low	$4.0 \times t_{SCLK} - 4$		ns
t_{WC}^1 \overline{AWE} Low to \overline{AWE} Low	$(WR_DLY + 5.0) \times t_{SCLK} - 4$		ns
t_{DWS}^1 Data Setup Time for a Write Access	$(WR_DLY + 1.5) \times t_{SCLK} - 4$		ns
t_{DWH} Data Hold Time for a Write Access	$2.5 \times t_{SCLK} - 4$		ns
Read Cycle			
<i>Switching Characteristics</i>			
t_{CRL} ND_CE Setup Time to \overline{ARE} Low	$1.0 \times t_{SCLK} - 4$		ns
t_{CRH} ND_CE Hold Time from \overline{ARE} High	$3.0 \times t_{SCLK} - 4$		ns
t_{RP}^1 \overline{ARE} Low to \overline{ARE} High	$(RD_DLY + 1.0) \times t_{SCLK} - 4$		ns
t_{RHRL} \overline{ARE} High to \overline{ARE} Low	$4.0 \times t_{SCLK} - 4$		ns
t_{RC}^1 \overline{ARE} Low to \overline{ARE} Low	$(RD_DLY + 5.0) \times t_{SCLK} - 4$		ns
<i>Timing Requirements</i>			
t_{DRS} Data Setup Time for a Read Transaction	8.0		ns
t_{DRH} Data Hold Time for a Read Transaction	0.0		ns
Write Followed by Read			
<i>Switching Characteristic</i>			
t_{WHRL} \overline{AWE} High to \overline{ARE} Low	$5.0 \times t_{SCLK} - 4$		ns

¹ WR_DLY and RD_DLY are defined in the NFC_CTL register.

Synchronous Burst AC Timing

Table 37 and Figure 28 on Page 57 describe Synchronous Burst AC operations.

Table 37. Synchronous Burst AC Timing

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
t_{NDS}	DATA15-0 Setup Before NR_CLK	4.0		ns
t_{NDH}	DATA15-0 Hold After NR_CLK	2.0		ns
t_{NWS}	WAIT Setup Before NR_CLK	8.0		ns
t_{NWH}	WAIT Hold After NR_CLK	0.0		ns
<i>Switching Characteristics</i>				
t_{NDO}	\overline{AMSx} , $\overline{ABE1-0}$, ADDR19-1, $\overline{NR_ADV}$, $\overline{NR_OE}$ Output Delay After NR_CLK	6.0		ns
t_{NHO}	$\overline{ABE1-0}$, ADDR19-1 Output Hold After NR_CLK	-3.0		ns

NOTE: NR_CLK dotted line represents a free running version of NR_CLK that is not visible on the NR_CLK pin.

Figure 28. Synchronous Burst AC Interface Timing

External DMA Request Timing

Table 38 and Figure 29 describe the external DMA request timing operations.

Table 38. External DMA Request Timing

Parameter		Min	Max	Unit
Timing Requirements				
t _{DS}	DMARx Asserted to CLKOUT High Setup	6.0		ns
t _{DH}	CLKOUT High to DMARx Deasserted Hold Time	0.0		ns
t _{DMARACT}	DMARx Active Pulse Width	1.0 × t _{SCLK}		ns
t _{DMARINACT}	DMARx Inactive Pulse Width	1.75 × t _{SCLK}		ns

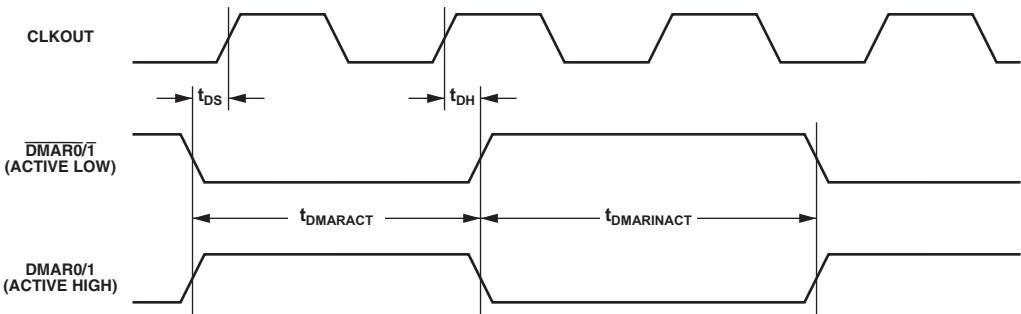

Figure 29. External DMA Request Timing

Serial Ports Timing

Table 40 through Table 43 on Page 63 and Figure 34 on Page 62 through Figure 37 on Page 64 describe serial port operations.

Table 40. Serial Ports—External Clock

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SFSE} TFSx/RFSx Setup Before TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	3.0		ns
t_{HFSE} TFSx/RFSx Hold After TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	3.0		ns
t_{SDRE} Receive Data Setup Before RSCLKx ¹	3.0		ns
t_{HDRE} Receive Data Hold After RSCLKx ¹	3.0		ns
t_{SCLKEW} TSCLKx/RSCLKx Width	4.5		ns
t_{SCLKE} TSCLKx/RSCLKx Period	15.0 ²		ns
t_{SUDTE} Start-Up Delay From SPORT Enable To First External TFSx	$4 \times t_{SCLKE}$		ns
t_{SUDRE} Start-Up Delay From SPORT Enable To First External RFSx	$4 \times t_{RCLKE}$		ns
<i>Switching Characteristics</i>			
t_{DFSE} TFSx/RFSx Delay After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ³		10.0	ns
t_{HOFSE} TFSx/RFSx Hold After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ³	0.0		ns
t_{DDTE} Transmit Data Delay After TSCLKx ³		10.0	ns
t_{HDTE} Transmit Data Hold After TSCLKx ³	0.0		ns

¹ Referenced to sample edge.

² For receive mode with external RSCLKx and external RFSx only, the maximum specification is 11.11 ns (90 MHz).

³ Referenced to drive edge.

Table 41. Serial Ports—Internal Clock

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SFSI} TFSx/RFSx Setup Before TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	10.0		ns
t_{HFSI} TFSx/RFSx Hold After TSCLKx/RSCLKx (Externally Generated TFSx/RFSx) ¹	–1.5		ns
t_{SDRI} Receive Data Setup Before RSCLKx ¹	10.0		ns
t_{HDRI} Receive Data Hold After RSCLKx ¹	–1.5		ns
<i>Switching Characteristics</i>			
t_{DFSI} TFSx/RFSx Delay After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ²		3.0	ns
t_{HOFSI} TFSx/RFSx Hold After TSCLKx/RSCLKx (Internally Generated TFSx/RFSx) ²	–1.0		ns
t_{DDTI} Transmit Data Delay After TSCLKx ²		3.0	ns
t_{HDTI} Transmit Data Hold After TSCLKx ²	–2.0		ns
t_{SCLKIW} TSCLKx/RSCLKx Width	4.5		ns

¹ Referenced to sample edge.

² Referenced to drive edge.

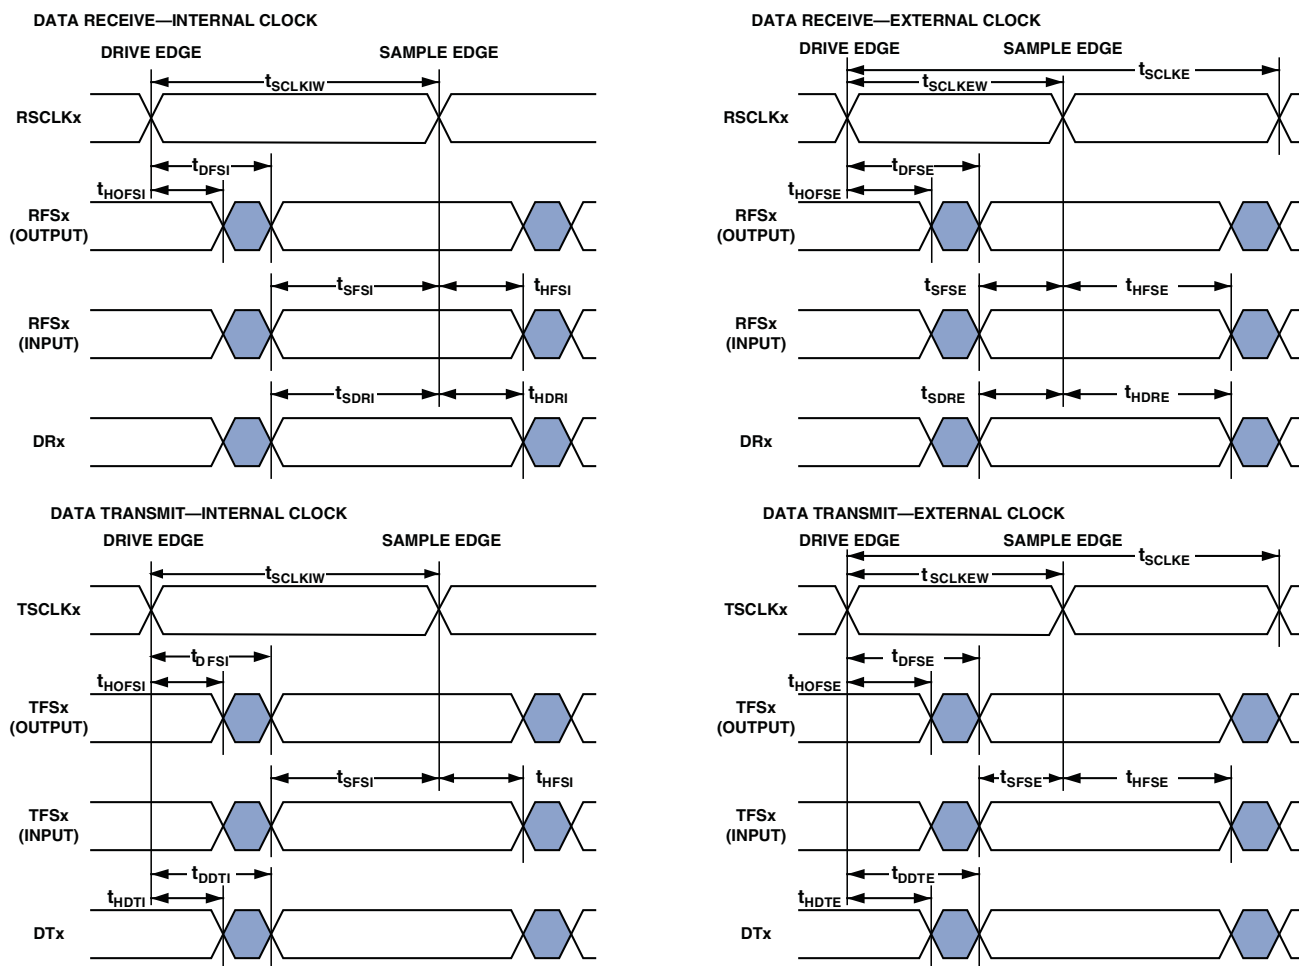

Figure 35. Serial Ports

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Table 42. Serial Ports—Enable and Three-State

Parameter		Min	Max	Unit
<i>Switching Characteristics</i>				
t_{DTENE}	Data Enable Delay from External TSCLKx ¹	0		ns
t_{DDTTE}	Data Disable Delay from External TSCLKx ^{1, 2, 3}		10	ns
t_{DTENI}	Data Enable Delay from Internal TSCLKx ¹	-2		ns
t_{DDTTI}	Data Disable Delay from Internal TSCLKx ^{1, 2, 3}		3	ns

¹ Referenced to drive edge.

² Applicable to multichannel mode only.

³ TSCLKx is tied to RSCLKx.

Figure 36. Serial Ports—Enable and Three-State

Table 43. Serial Ports—External Late Frame Sync

Parameter		Min	Max	Unit
<i>Switching Characteristics</i>				
$t_{DDTLFSE}$	Data Delay from Late External TFSx or External RFSx in multi-channel mode with MFD = 0 ^{1, 2}		10.0	ns
$t_{DTENLFSE}$	Data Enable from External RFSx in multi-channel mode with MFD = 0 ^{1, 2}	0		ns

¹ In multichannel mode, TFSx enable and TFSx valid follow $t_{DTENLFS}$ and $t_{DDTLFSE}$.

² If external RFS/TFS setup to $RSCLK/TSCLK > t_{SCLK}/2$, then $t_{DDTTE/I}$ and $t_{DTENE/I}$ apply; otherwise $t_{DDTLFSE}$ and $t_{DTENLFS}$ apply.

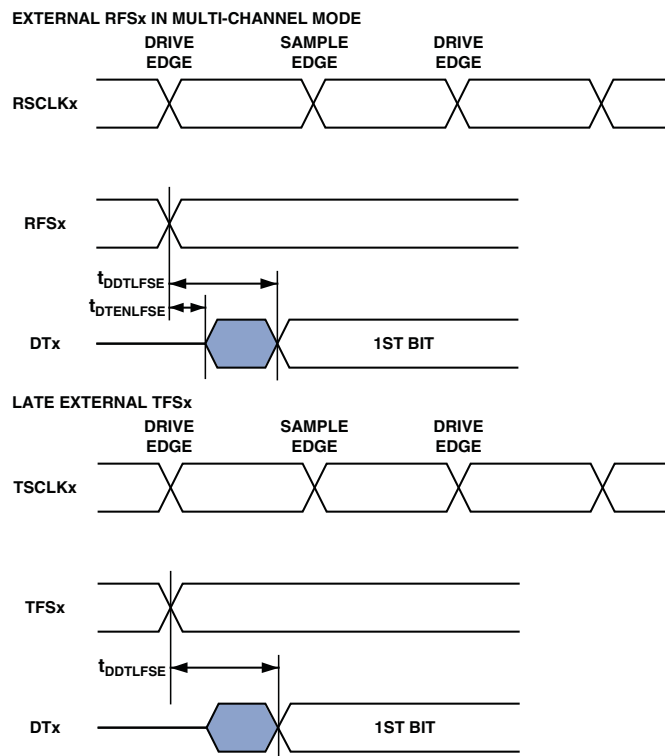

Figure 37. Serial Ports—External Late Frame Sync

Serial Peripheral Interface (SPI) Port—Master Timing

Table 44 and Figure 38 describe SPI port master operations.

Table 44. Serial Peripheral Interface (SPI) Port—Master Timing

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SSPIDM} Data Input Valid to SPIxSCK Edge (Data Input Setup)	9.0		ns
t_{HSPIDM} SPIxSCK Sampling Edge to Data Input Invalid	-1.5		ns
<i>Switching Characteristics</i>			
t_{SDSCIM} $\overline{\text{SPIxSELY}}$ Low to First SPIxSCK Edge	$2t_{SCLK}-1.5$		ns
t_{SPICHM} SPIxSCK High Period	$2t_{SCLK}-1.5$		ns
t_{SPICLM} SPIxSCK Low Period	$2t_{SCLK}-1.5$		ns
t_{SPICLK} SPIxSCK Period	$4t_{SCLK}-1.5$		ns
t_{HDSM} Last SPIxSCK Edge to $\overline{\text{SPIxSELY}}$ High	$2t_{SCLK}-1.5$		ns
t_{SPITDM} Sequential Transfer Delay	$2t_{SCLK}-1.5$		ns
$t_{DDSPIDM}$ SPIxSCK Edge to Data Out Valid (Data Out Delay)		6	ns
$t_{HDSPIDM}$ SPIxSCK Edge to Data Out Invalid (Data Out Hold)	-1.0		ns

Figure 38. Serial Peripheral Interface (SPI) Port—Master Timing

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Serial Peripheral Interface (SPI) Port—Slave Timing

Table 45 and Figure 39 describe SPI port slave operations.

Table 45. Serial Peripheral Interface (SPI) Port—Slave Timing

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
$t_{SPICHHS}$ SPIxSCK High Period	$2t_{SCLK} - 1.5$		ns
t_{SPICLS} SPIxSCK Low Period	$2t_{SCLK} - 1.5$		ns
t_{SPICLK} SPIxSCK Period	$4t_{SCLK}$		ns
t_{HDS} Last SPIxSCK Edge to \overline{SPIxSS} Not Asserted	$2t_{SCLK} - 1.5$		ns
t_{SPITDS} Sequential Transfer Delay	$2t_{SCLK} - 1.5$		ns
t_{SDSCI} \overline{SPIxSS} Assertion to First SPIxSCK Edge	$2t_{SCLK} - 1.5$		ns
t_{SSPID} Data Input Valid to SPIxSCK Edge (Data Input Setup)	1.6		ns
t_{HSPID} SPIxSCK Sampling Edge to Data Input Invalid	1.6		ns
<i>Switching Characteristics</i>			
t_{DSOE} \overline{SPIxSS} Assertion to Data Out Active	0	8	ns
t_{DSDHI} \overline{SPIxSS} Deassertion to Data High Impedance	0	8	ns
t_{DDSPID} SPIxSCK Edge to Data Out Valid (Data Out Delay)		10	ns
t_{HDSPID} SPIxSCK Edge to Data Out Invalid (Data Out Hold)	0		ns

Figure 39. Serial Peripheral Interface (SPI) Port—Slave Timing

Universal Asynchronous Receiver-Transmitter (UART) Ports—Receive and Transmit Timing

The UART ports have a maximum baud rate of $SCLK/16$. There is some latency between the generation of internal UART interrupts and the external data operations. These latencies are negligible at the data transmission rates for the UART. For more information, see the *ADSP-BF54x Blackfin Processor Hardware Reference*.

General-Purpose Port Timing

Table 46 and Figure 40 describe general-purpose port operations.

Table 46. General-Purpose Port Timing

Parameter	Min	Max	Unit
<i>Timing Requirement</i>			
t_{WFI} General-Purpose Port Pin Input Pulse Width	$t_{SCLK} + 1$		ns
<i>Switching Characteristic</i>			
t_{GPOD} General-Purpose Port Pin Output Delay from CLKOUT Low	-0.3	+6	ns

Figure 40. General-Purpose Port Timing

Timer Clock Timing

Table 47 and Figure 41 describe timer clock timing.

Table 47. Timer Clock Timing

Parameter	Min	Max	Unit
Switching Characteristic			
tTODP Timer Output Update Delay After PPI_CLK High		15	ns

Figure 41. Timer Clock Timing

Timer Cycle Timing

Table 48 and Figure 42 describe timer expired operations. The input signal is asynchronous in “width capture mode” and “external clock mode” and has an absolute maximum input frequency of ($f_{SCLK}/2$) MHz.

Table 48. Timer Cycle Timing

Parameter		Min	Max	Unit
<i>Timing Characteristics</i>				
t_{WL}	Timer Pulse Width Input Low ¹	$1 \times t_{SCLK}$		ns
t_{WH}	Timer Pulse Width Input High ¹	$1 \times t_{SCLK}$		ns
t_{TIS}	Timer Input Setup Time Before CLKOUT Low ²	6.5		ns
t_{TIH}	Timer Input Hold Time After CLKOUT Low ²	-1		ns
<i>Switching Characteristics</i>				
t_{HTO}	Timer Pulse Width Output	$1 \times t_{SCLK}$	$(2^{32} - 1) \times t_{SCLK}$	ns
t_{TOD}	Timer Output Delay After CLKOUT High		6	ns

¹ The minimum pulse widths apply for TMRx signals in width capture and external clock modes.

² Either a valid setup and hold time or a valid pulse width is sufficient. There is no need to resynchronize timer flag inputs.

Figure 42. Timer Cycle Timing

Up/Down Counter/Rotary Encoder Timing

Table 49 and Figure 43 describe up/down counter/rotary encoder timing.

Table 49. Up/Down Counter/Rotary Encoder Timing

Parameter		Min	Max	Unit
Timing Requirements				
t _{WCOUNT}	CUD/CDG/CZM Input Pulse Width	t _{SCLK} + 1		ns
t _{CIS}	CUD/CDG/CZM Input Setup Time Before CLKOUT High ¹	7.2		ns
t _{CIH}	CUD/CDG/CZM Input Hold Time After CLKOUT High ¹	0.0		ns

¹ Either a valid setup and hold time or a valid pulse width is sufficient. There is no need to resynchronize counter inputs.

Figure 43. Up/Down Counter/Rotary Encoder Timing

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

SD/SDIO Controller Timing

Table 50 and Figure 44 describe SD/SDIO controller timing.

Table 51 and Figure 45 describe SD/SDIO controller (high-speed mode) timing.

Table 50. SD/SDIO Controller Timing

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{ISU} SD_Dx and SD_CMD Input Setup Time	7.2		ns
t_{IH} SD_Dx and SD_CMD Input Hold Time	2		ns
<i>Switching Characteristics</i>			
f_{PP} SD_CLK Frequency During Data Transfer Mode ¹	0	20	MHz
f_{PP} SD_CLK Frequency During Identification Mode ¹	100 ²	400	kHz
t_{WL} SD_CLK Low Time	15		ns
t_{WH} SD_CLK High Time	15		ns
t_{TLH} SD_CLK Rise Time		10	ns
t_{THL} SD_CLK Fall Time		10	ns
t_{ODLY} SD_Dx and SD_CMD Output Delay Time During Data Transfer Mode	-1	+14	ns
SD_Dx and SD_CMD Output Delay Time During Identification Mode	-1	+50	ns

¹ $t_{PP}=1/f_{PP}$.

² Spec can be 0 kHz, meaning to stop the clock. The given minimum frequency range is for cases where a continuous clock is required.

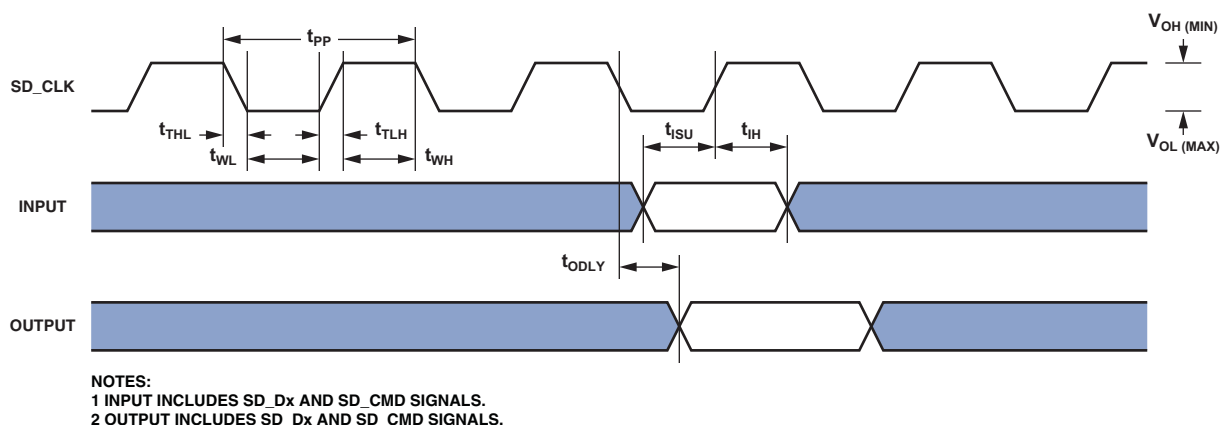

Figure 44. SD/SDIO Controller Timing

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

Table 51. SD/SDIO Controller Timing (High Speed Mode)

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
t_{ISU}	SD_Dx and SD_CMD Input Setup Time	7.2		ns
t_{IH}	SD_Dx and SD_CMD Input Hold Time	2		ns
<i>Switching Characteristics</i>				
f_{PP}	SD_CLK Frequency During Data Transfer Mode ¹	0	40	MHz
t_{WL}	SD_CLK Low Time	9.5		ns
t_{WH}	SD_CLK High Time	9.5		ns
t_{TLH}	SD_CLK Rise Time		3	ns
t_{THL}	SD_CLK Fall Time		3	ns
t_{ODLY}	SD_Dx and SD_CMD Output Delay Time During Data Transfer Mode		2	ns
t_{OH}	SD_Dx and SD_CMD Output Hold Time	2.5		ns

¹ $t_{PP} = 1/f_{PP}$.

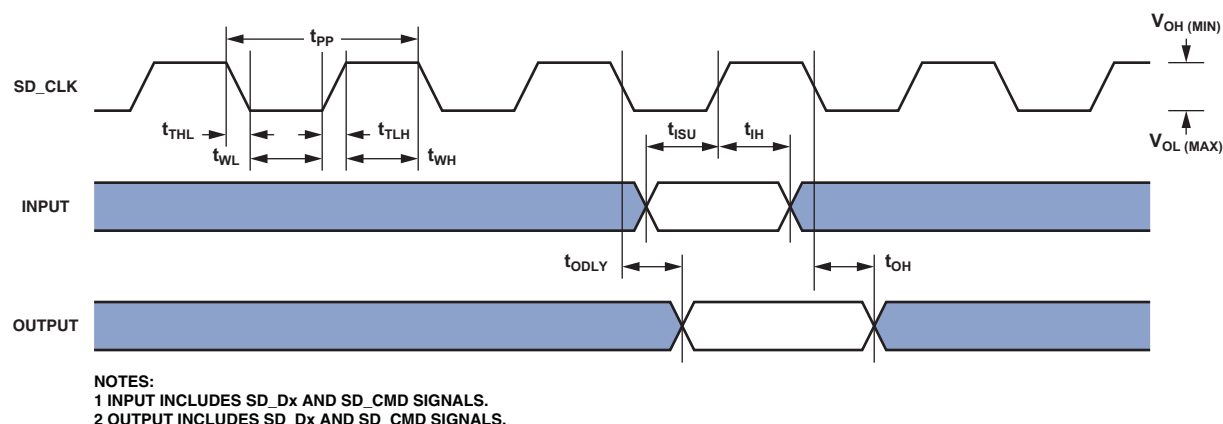

Figure 45. SD/SDIO Controller Timing (High Speed Mode)

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

MXVR Timing

Table 52 and Table 53 describe the MXVR timing requirements.
Figure 5 illustrates the MOST connection.

Table 52. MXVR Timing—MXI Center Frequency Requirements

Parameter		Fs = 38 kHz	Fs = 44.1 kHz	Fs = 48 kHz	Unit
f _{MXI_256}	MXI Center Frequency (256 Fs)	9.728	11.2896	12.288	MHz
f _{MXI_384}	MXI Center Frequency (384 Fs)	14.592	16.9344	18.432	MHz
f _{MXI_512}	MXI Center Frequency (512 Fs)	19.456	22.5792	24.576	MHz
f _{MXI_1024}	MXI Center Frequency (1024 Fs)	38.912	45.1584	49.152	MHz

Table 53. MXVR Timing—MXI Clock Requirements

Parameter		Min	Max	Unit
<i>Timing Requirements</i>				
FS _{MXI}	MXI Clock Frequency Stability	−50	+50	ppm
FT _{MXI}	MXI Frequency Tolerance Over Temperature	−300	+300	ppm
DC _{MXI}	MXI Clock Duty Cycle	+40	+60	%

ADSP-BF542/ADSP-BF544/ADSP-BF547/ADSP-BF548/ADSP-BF549

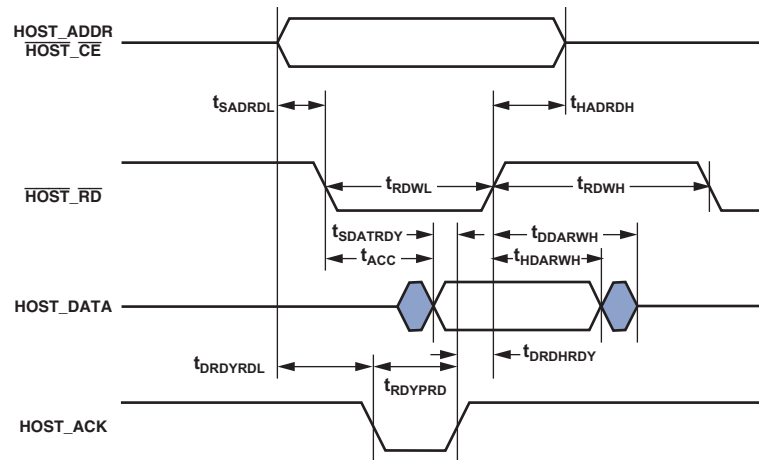

HOSTDP A/C Timing-Host Read Cycle

Table 54 and Figure 46 describe the HOSTDP A/C host read cycle timing requirements.

Table 54. Host Read Cycle Timing Requirements

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SADRDL} HOST_ADDR and $\overline{HOST_CE}$ Setup Before $\overline{HOST_RD}$ Falling Edge	4		ns
t_{HADRDL} HOST_ADDR and $\overline{HOST_CE}$ Hold After $\overline{HOST_RD}$ Rising Edge	2.5		ns
t_{RDWL} $\overline{HOST_RD}$ Pulse Width Low (ACK Mode)	$t_{DRDYRDL} + t_{RDYPRD} + t_{DRDHRDY}$		ns
t_{RDWL} $\overline{HOST_RD}$ Pulse Width Low (INT Mode)	$1.5 \times t_{SCLK} + 8.7$		ns
t_{RDWH} $\overline{HOST_RD}$ Pulse Width High or Time Between $\overline{HOST_RD}$ Rising Edge and $\overline{HOST_WR}$ Falling Edge	$2 \times t_{SCLK}$		ns
$t_{DRDHRDY}$ $\overline{HOST_RD}$ Rising Edge Delay After HOST_ACK Rising Edge (ACK Mode)	0		ns
<i>Switching Characteristics</i>			
$t_{SDATRDY}$ HOST_D15–0 Valid Prior HOST_ACK Rising Edge (ACK Mode)	$t_{SCLK} - 4.0$		ns
$t_{DRDYRDL}$ HOST_ACK Falling Edge After $\overline{HOST_CE}$ (ACK Mode)		11.25	ns
t_{RDYPRD} HOST_ACK Low Pulse-Width for Read Access (ACK Mode)		NM ¹	ns
t_{DDARWH} HOST_D15–0 Disable After $\overline{HOST_RD}$		8.0	ns
t_{ACC} HOST_D15–0 Valid After $\overline{HOST_RD}$ Falling Edge (INT Mode)		$1.5 \times t_{SCLK}$	ns
t_{HDARWH} HOST_D15–0 Hold After $\overline{HOST_RD}$ Rising Edge	1.0		ns

¹ NM (Not Measured) — This parameter is based on t_{SCLK} . It is not measured because the number of SCLK cycles for which HOST_ACK remains low depends on the Host DMA FIFO status. This is system design dependent.

In Figure 46, HOST_DATA is HOST_D0–D15.

Figure 46. HOSTDP A/C—Host Read Cycle

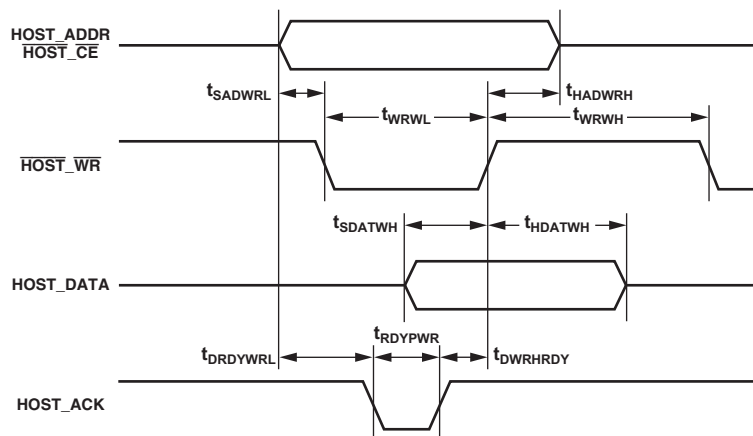

HOSTDP A/C Timing-Host Write Cycle

Table 55 and Figure 47 describe the HOSTDP A/C host write cycle timing requirements.

Table 55. Host Write Cycle Timing Requirements

Parameter	Min	Max	Unit
<i>Timing Requirements</i>			
t_{SADWRL} HOST_ADDR/HOST_CE Setup Before HOST_WR Falling Edge	4		ns
t_{HADWRH} HOST_ADDR/HOST_CE Hold After HOST_WR Rising Edge	2.5		ns
t_{WRWL} HOST_WR Pulse Width Low (ACK Mode)	$t_{DRDYWRL} + t_{RDYPRD} + t_{DWRHRDY}$		ns
HOST_WR Pulse Width Low (INT Mode)	$1.5 \times t_{SCLK} + 8.7$		ns
t_{WRWH} HOST_WR Pulse Width High or Time Between HOST_WR Rising Edge and HOST_RD Falling Edge	$2 \times t_{SCLK}$		ns
$t_{DWRHRDY}$ HOST_WR Rising Edge Delay After HOST_ACK Rising Edge (ACK Mode)	0		ns
t_{HDATWH} HOST_D15–0 Hold After HOST_WR Rising Edge	2.5		ns
t_{SDATWH} HOST_D15–0 Setup Before HOST_WR Rising Edge	3.5		ns
<i>Switching Characteristics</i>			
$t_{DRDYWRL}$ HOST_ACK Falling Edge After HOST_CE Asserted (ACK Mode)		11.25	ns
t_{RDYPWR} HOST_ACK Low Pulse-Width for Write Access (ACK Mode)		NM ¹	ns

¹ NM (not measured)—This parameter is based on t_{SCLK} . It is not measured because the number of SCLK cycles for which HOST_ACK remains low depends on the Host DMA FIFO status. This is system design dependent.

In Figure 47, HOST_DATA is HOST_D0–D15.

Figure 47. HOSTDP A/C- Host Write Cycle

ATA/ATAPI-6 Interface Timing

The following tables and figures specify ATAPI timing parameters. For detailed parameter descriptions, refer to the ATAPI specification (ANSI INCITS 361-2002). [Table 58](#) to [Table 61](#) include ATAPI timing parameter equations. System designers should use these equations along with the parameters provided

in [Table 56](#) and [Table 57](#). ATAPI timing control registers should be programmed such that ANSI INCITS 361-2002 specifications are met for the desired transfer type and mode.

Table 56. ATA/ATAPI-6 Timing Parameters

Parameter	Min	Max	Unit
t_{SK1} Difference in output delay after CLKOUT for ATAPI output pins ¹		6	ns
t_{OD} Output delay after CLKOUT for outputs ¹		12	ns
t_{SUD} $\overline{\text{ATAPI_D0-15}}$ or $\overline{\text{ATAPI_D0-15A}}$ Setup Before CLKOUT	6		ns
t_{SUI} $\overline{\text{ATAPI_IORDY}}$ Setup Before CLKOUT	6		ns
t_{SUDU} $\overline{\text{ATAPI_D0-15}}$ or $\overline{\text{ATAPI_D0-15A}}$ Setup Before $\overline{\text{ATAPI_IORDY}}$ (UDMA-in only)	2		ns
t_{HDU} $\overline{\text{ATAPI_D0-15}}$ or $\overline{\text{ATAPI_D0-15A}}$ Hold After $\overline{\text{ATAPI_IORDY}}$ (UDMA-in only)	2.6		ns

¹ ATAPI output pins include $\overline{\text{ATAPI_CS0}}$, $\overline{\text{ATAPI_CS1}}$, A1-3, $\overline{\text{ATAPI_DIOR}}$, $\overline{\text{ATAPI_DIOW}}$, $\overline{\text{ATAPI_DMACK}}$, $\overline{\text{ATAPI_D0-15}}$, $\overline{\text{ATAPI_A0-2A}}$, and $\overline{\text{ATAPI_D0-15A}}$.

Table 57. ATA/ATAPI-6 System Timing Parameters

Parameter	Source
t_{SK2} Maximum difference in board propagation delay between any 2 ATAPI output pins ¹	System Design
t_{BD} Maximum board propagation delay.	System Design
t_{SK3} Maximum difference in board propagation delay during a read between $\overline{\text{ATAPI_IORDY}}$ and $\overline{\text{ATAPI_D0-15/ATAPI_D0-15A}}$.	System Design
t_{SK4} Maximum difference in ATAPI cable propagation delay between output pin group A and output pin group B ²	ATAPI Cable Specification
t_{CDD} ATAPI cable propagation delay for $\overline{\text{ATAPI_D0-15}}$ and $\overline{\text{ATAPI_D0-15A}}$ signals.	ATAPI Cable Specification
t_{CDC} ATAPI cable propagation delay for $\overline{\text{ATAPI_DIOR}}$, $\overline{\text{ATAPI_DIOW}}$, $\overline{\text{ATAPI_IORDY}}$, and $\overline{\text{ATAPI_DMACK}}$ signals.	ATAPI Cable Specification

¹ ATAPI output pins include $\overline{\text{ATAPI_CS0}}$, $\overline{\text{ATAPI_CS1}}$, A1-3, $\overline{\text{ATAPI_DIOR}}$, $\overline{\text{ATAPI_DIOW}}$, $\overline{\text{ATAPI_DMACK}}$, $\overline{\text{ATAPI_D0-15}}$, $\overline{\text{ATAPI_A0-2A}}$, and $\overline{\text{ATAPI_D0-15A}}$.

² Output pin group A includes $\overline{\text{ATAPI_DIOR}}$, $\overline{\text{ATAPI_DIOW}}$, and $\overline{\text{ATAPI_DMACK}}$. TEST CONDITIONS

All timing parameters appearing in this data sheet were measured under the conditions described in this section. Figure 72 shows the measurement point for AC measurements (except output enable/disable). The measurement point V_{MEAS} is $V_{DDEXT}/2$ or $V_{DDDDR}/2$, depending on the pin under test.

Figure 72. Voltage Reference Levels for AC Measurements
(Except Output Enable/Disable)

Output Enable Time

Output pins are considered to be enabled when they have made a transition from a high-impedance state to the point when they start driving. The output enable time t_{ENA} is the interval from the point when a reference signal reaches a high or low voltage level to the point when the output starts driving as shown in the output enable/disable diagram (Figure 73). The time, $t_{ENA_MEASURED}$, is the interval from the point when the reference signal switches to the point when the output voltage reaches either 1.75 V (output high) or 1.25 V (output low). Time t_{TRIP} is the interval from when the output starts driving to when the output reaches the 1.25 V or 1.75 V trip voltage. Time t_{ENA} is calculated as shown in the equation:

$$t_{ENA} = t_{ENA_MEASURED} - t_{TRIP}$$

If multiple pins (such as the data bus) are enabled, the measurement value is that of the first pin to start driving.

Output Disable Time

Output pins are considered to be disabled when they stop driving, go into a high-impedance state, and start to decay from their output high or low voltage. The time for the voltage on the bus to decay by ΔV is dependent on the capacitive load, C_L and the load current, I_L . This decay time can be approximated by the equation:

$$t_{DECAY} = (C_L \Delta V) / I_L$$

The output disable time t_{DIS} is the difference between $t_{DIS_MEASURED}$ and t_{DECAY} as shown in Figure 73. The time $t_{DIS_MEASURED}$ is the interval from when the reference signal switches to when the output voltage decays ΔV from the measured output high or output low voltage. The time t_{DECAY} is calculated with test loads C_L and I_L , and with ΔV equal to 0.25 V.

Figure 73. Output Enable/Disable

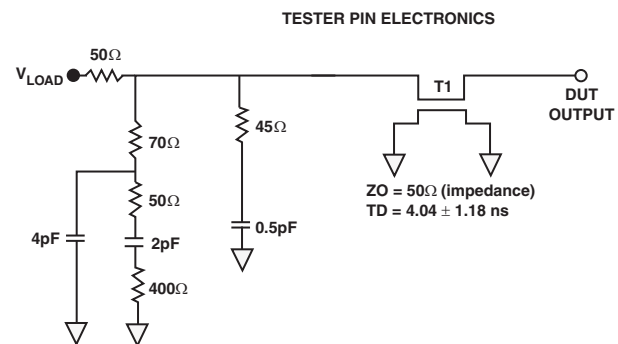

Example System Hold Time Calculation

To determine the data output hold time in a particular system, first calculate t_{DECAY} using the equation given above. Choose ΔV to be the difference between the ADSP-BF54x Blackfin processors' output voltage and the input threshold for the device requiring the hold time. A typical ΔV will be 0.4 V. C_L is the total bus capacitance (per data line), and I_L is the total leakage or three-state current (per data line). The hold time will be t_{DECAY} plus the minimum disable time (for example, t_{DDAT} for an asynchronous memory write cycle).

CAPACITIVE LOADING

Output delays and holds are based on standard capacitive loads of an average of 6 pF on all balls (see Figure 74).

V_{LOAD} is equal to $V_{DDEXT}/2$ or $V_{DDDDR}/2$, depending on the pin under test.

NOTES:
THE WORST-CASE TRANSMISSION LINE DELAY IS SHOWN AND CAN BE USED FOR THE OUTPUT TIMING ANALYSIS TO REFLECT THE TRANSMISSION LINE EFFECT AND MUST BE CONSIDERED. THE TRANSMISSION LINE (TD), IS FOR LOAD ONLY AND DOES NOT AFFECT THE DATA SHEET TIMING SPECIFICATIONS.

ANALOG DEVICES RECOMMENDS USING THE IBIS MODEL TIMING FOR A GIVEN SYSTEM REQUIREMENT. IF NECESSARY, A SYSTEM MAY INCORPORATE EXTERNAL DRIVERS TO COMPENSATE FOR ANY TIMING DIFFERENCES.

Figure 74. Equivalent Device Loading for AC Measurements
(Includes All Fixtures)

TYPICAL RISE AND FALL TIMES

Figure 75 through Figure 86 on Page 93 show how output rise time varies with capacitance. The delay and hold specifications given should be derated by a factor derived from these figures. The graphs in these figures may not be linear outside the ranges shown.

THERMAL CHARACTERISTICS

To determine the junction temperature on the application printed circuit board use

$$T_J = T_{CASE} + (\Psi_{JT} \times P_D)$$

where:

T_J = junction temperature ($^{\circ}\text{C}$)

T_{CASE} = case temperature ($^{\circ}\text{C}$) measured by customer at top center of package.

Ψ_{JT} = from Table 64

P_D = power dissipation. (See Table 17 on Page 38 for a method to calculate P_D .)

Values of θ_{JA} are provided for package comparison and printed circuit board design considerations. θ_{JA} can be used for a first order approximation of T_J by the equation

$$T_J = T_A + (\theta_{JA} \times P_D)$$

where:

T_A = ambient temperature ($^{\circ}\text{C}$)

Table 64 lists values for θ_{JC} and θ_{JB} parameters. These values are provided for package comparison and printed circuit board design considerations. Airflow measurements in Table 64 comply with JEDEC standards JESD51-2 and JESD51-6, and the junction-to-board measurement complies with JESD51-8. The junction-to-case measurement complies with MIL-STD-883 (Method 1012.1). All measurements use a 2S2P JEDEC testboard.

Table 64. Thermal Characteristics, 400-Ball CSP_BGA

Parameter	Condition	Typical	Unit
θ_{JA}	0 linear m/s air flow	18.4	$^{\circ}\text{C/W}$
	1 linear m/s air flow	15.8	$^{\circ}\text{C/W}$
	2 linear m/s air flow	15.0	$^{\circ}\text{C/W}$
θ_{JB}		9.75	$^{\circ}\text{C/W}$
θ_{JC}		6.37	$^{\circ}\text{C/W}$
Ψ_{JT}	0 linear m/s air flow	0.27	$^{\circ}\text{C/W}$
	1 linear m/s air flow	0.60	$^{\circ}\text{C/W}$
	2 linear m/s air flow	0.66	$^{\circ}\text{C/W}$

OUTLINE DIMENSIONS

Dimensions for the 17 mm × 17 mm CSP_BGA package in Figure 88 are shown in millimeters.

COMPLIANT TO JEDEC STANDARDS MO-275-MMAB-1.

Figure 88. 400-Ball, 17 mm × 17 mm CSP_BGA (Chip Scale Package Ball Grid Array) (BC-400-1)

SURFACE-MOUNT DESIGN

Table 67 is provided as an aid to PCB design. For industry-standard design recommendations, refer to IPC-7351, *Generic Requirements for Surface-Mount Design and Land Pattern Standard*.

Table 67. BGA Data for Use with Surface-Mount Design

Package	Package Ball Attach Type	Package Solder Mask Opening	Package Ball Pad Size
400-Ball CSP_BGA (Chip Scale Package Ball Grid Array) BC-400-1	Solder Mask Defined	0.40 mm Diameter	0.50 mm Diameter

AUTOMOTIVE PRODUCTS

The ADSP-BF542, ADSP-BF544, and the ADSP-BF549 models are available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that these automotive models may have specifications that differ from the commercial models and designers should review the product Specifications section of this data sheet carefully.

Only the automotive grade products shown in [Table 68](#) are available for use in automotive applications. Contact your local ADI account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for these models.

Table 68. Automotive Products

Product Family ^{1, 2}	Temperature Range ³	Speed Grade (Max)	Package Description	Package Option
ADBF542WBBCZ4xx	–40°C to +85°C	400 MHz	400-Ball CSP_BGA	BC-400-1
ADBF542WBBCZ5xx	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADBF544WBBCZ5xx	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADBF549WBBCZ5xx	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADBF549MWBBCZ5xx	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1

¹ Z = RoHS compliant part.

² The use of xx designates silicon revision.

³ Referenced temperature is ambient temperature.

ORDERING GUIDE

Model ^{1, 2, 3, 4}	Temperature Range ^{5, 6}	Speed Grade (Max)	Package Description	Package Option
ADSP-BF542BBCZ-4A	–40°C to +85°C	400 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF542BBCZ-5A	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF542MBBCZ-5M	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1

ADSP-BF547YBC-4A	–40°C to +105°C	400 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF547YBCZ-4A	–40°C to +105°C	400 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF548MBBCZ-5M	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF548BBCZ-5A	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1
ADSP-BF548BBCZ-5AA	–40°C to +85°C	533 MHz	400-Ball CSP_BGA	BC-400-1

¹ Each ADSP-BF54xM model contains a mobile DDR controller and does not support the use of standard DDR memory.

² Z = RoHS compliant part.

³ The ADSP-BF549 is available for automotive use only. Please contact your local ADI product representative or authorized distributor for specific automotive product ordering information.

⁴ AA = low Alpha Package.

⁵ Referenced temperature is ambient temperature.

⁶ Temperature range –40°C to +105°C is classified as extended temperature range.
