Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Detailed Description

The MAX3030E-MAX3033E are high-speed quad RS-422 transmitters designed for digital data transmission over balanced lines. They are designed to meet the requirements of TIA/EIA-422-B and ITU-T V.11. The MAX3030E-MAX3033E are available in two pinouts to be compatible with both the 26LS31 and SN75174 industry-standard devices. Both are offered in 20Mbps and 2Mbps baud rate. All versions feature a low-static current consumption ($I_{CC} < 100\mu A$) that makes them ideal for battery-powered and power-conscious applications. The 20Mbps version has a maximum propagation delay of 16ns and a part-to-part skew less than 5ns, allowing these devices to drive parallel data. The 2Mbps version is slow-rate-limited to reduce EMI and reduce reflections caused by improperly terminated cables.

Outputs have enhanced ESD protection providing $\pm 15kV$ tolerance. All parts feature hot-swap capability that eliminates false transitions on the data cable during power-up or hot insertion.

±15kV ESD Protection

As with all Maxim devices, ESD-protection structures are incorporated on all pins to protect against electrostatic discharges encountered during handling and assembly. The driver outputs and receiver inputs have extra protection against static electricity. Maxim's engineers developed state-of-the-art structures to protect these pins against ESD of $\pm 15kV$ without damage. The ESD structures withstand high ESD in all states: normal operation and power-down. After an ESD event, the MAX3030E-MAX3033E keep working without latchup. ESD protection can be tested in various ways; the

transmitter outputs of this product family are characterized for protection to $\pm 15kV$ using the Human Body Model. Other ESD test methodologies include IEC10004-2 Contact Discharge and IEC1000-4-2 Air-Gap Discharge (formerly IEC801-2).

ESD Test Conditions

ESD performance depends on a variety of conditions. Contact Maxim for a reliability report that documents test setup, test methodology, and test results.

Human Body Model

Figure 8 shows the Human Body Model, and Figure 9 shows the current waveform it generates when discharged into low impedance. This model consists of a 100pF capacitor charged to the ESD voltage of interest, which is then discharged into the test device through a 1.5k Ω resistor.

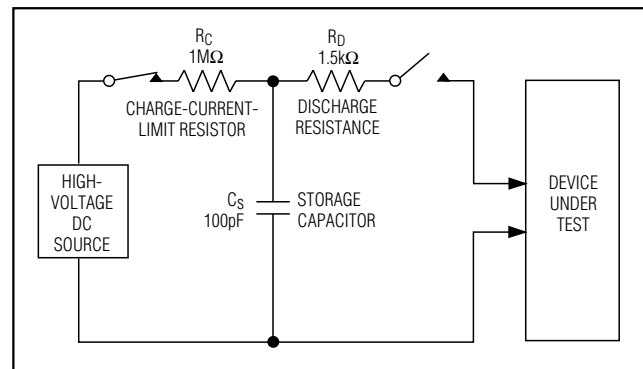

Figure 8. Human Body ESD Test Model

Figure 9. Human Body Current Waveform

±15kV ESD-Protected, 3.3V Quad RS-422 Transmitters

Machine Model

The Machine Model for ESD tests all pins using a 200pF storage capacitor and zero discharge resistance. Its objective is to emulate the stress caused by contact that occurs with handling and assembly during manufacturing. Of course, all pins require this protection during manufacturing, not just inputs and outputs. Therefore, after PC board assembly, the Machine Model is less relevant to I/O ports.

Hot Swap

When circuit boards are plugged into a “hot” backplane, there can be disturbances to the differential signal levels that could be detected by receivers connected to the transmission line. This erroneous data could cause data errors to an RS-422 system. To avoid this, the MAX3030E–MAX3033E have hot-swap capable inputs.

When a circuit board is plugged into a “hot” backplane, there is an interval during which the processor is going through its power-up sequence. During this time, the processor's output drivers are high impedance and are unable to drive the enable inputs of the MAX3030E–MAX3033E (EN, $\overline{\text{EN}}$, EN_) to defined logic levels. Leakage currents from these high-impedance drivers, of as much as 10μA, could cause the enable inputs of the MAX3030E–MAX3033E to drift high or low. Additionally, parasitic capacitance of the circuit board could cause capacitive coupling of the enable inputs to either GND or VCC. These factors could cause the enable inputs of the MAX3030E–MAX3033E to drift to levels that may enable the transmitter outputs. To avoid this problem, the hot-swap input provides a method of holding the enable inputs of the MAX3030E–MAX3033E in the disabled state as VCC ramps up. This hot-swap input is able to overcome the leakage currents and parasitic capacitances that can pull the enable inputs to the enabled state.

Hot-Swap Input Circuitry

In the MAX3030E–MAX3033E, the enable inputs feature hot-swap capability. At the input there are two NMOS devices, M1 and M2 (Figure 10). When VCC is ramping up from zero, an internal 6μs timer turns on M2 and sets the SR latch, which also turns on M1. Transistors M2, a 2mA current sink, and M1, a 100μA current sink, pull EN to GND through a 5.6kΩ resistor. M2 is designed to pull the EN input to the disabled state against an external parasitic capacitance of up to 100pF that is trying to enable the EN input. After 6μs, the timer turns M2 off and M1 remains on, holding the EN input low against three-state output leakages that might enable EN. M1 remains on until an external source overcomes the required input

Figure 10. Simplified Structure of the Driver Enable Pin (EN)

Figure 11. Differential Power-Up Glitch (Hot Swap)

current. At this time the SR latch resets and M1 turns off. When M1 turns off, EN reverts to a standard, high-impedance CMOS input. Whenever VCC drops below 1V, the hot-swap input is reset. The EN1&2 and EN3&4 input structures are identical to the EN input. For the $\overline{\text{EN}}$ input, there is a complementary circuit employing two PMOS devices pulling the $\overline{\text{EN}}$ input to VCC.

Hot-Swap Line Transient

The circuit of Figure 11 shows a typical offset termination used to guarantee a greater than 200mV offset when a line is not driven. The 50pF capacitor repre-

$\pm 15\text{kV}$ ESD-Protected, 3.3V Quad RS-422 Transmitters

sents the minimum parasitic capacitance that would exist in a typical application. In most cases, more capacitance exists in the system and reduces the magnitude of the glitch. During a “hot-swap” event when the driver is connected to the line and is powered up, the driver must not cause the differential signal to drop below 200mV (Figures 12 and 13).

Operation of Enable Pins

The MAX3030E–MAX3033E family has two enable-functional versions.

The MAX3030E/MAX3031E are compatible with 26LS31, where the two enable signals control all four transmitters (global enable).

The MAX3032E/MAX3033E are compatible with the SN75174. EN1&2 controls transmitters 1 and 2, and EN 3&4 controls transmitters 3 and 4 (dual enable).

Typical Applications

The MAX3030E–MAX3033E offer optimum performance when used with the MAX3094E/MAX3096 3.3V quad differential line receivers. Figure 14 shows a typical RS-422 connection for transmitting and receiving data.
