Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: Nonlinearity is defined from code 128 to code 65535 (full scale). See Applications Information.

Note 3: DAC switched between all 1s and all 0s. V_{FS} = 4.096V.

Note 4: Digital inputs at 0V or V_{CC}.

Note 5: Part is clocked with pin toggling between 1s and 0s, $\overline{CS}$/LD is low.

Note 6: Reference can be overdriven (see Applications Information).

Note 7: Guaranteed by design. Not subject to test.

Note 8: Guaranteed by correlation for other reference and supply conditions.

PIN FUNCTIONS

CLK (Pin 1): The TTL Level Input for the Serial Interface Clock.

D_{IN} (Pin 2): The TTL Level Input for the Serial Interface Data. Data on the D_{IN} pin is latched into the shift register on the rising edge of the serial clock and is loaded MSB first. The LTC1655/LTC1655L requires a 16-bit word.

$\overline{CS}$/LD (Pin 3): The TTL Level Input for the Serial Interface Enable and Load Control. When $\overline{CS}$/LD is low, the CLK signal is enabled, so the data can be clocked in. When $\overline{CS}$/LD is pulled high, data is loaded from the shift register into the DAC register, updating the DAC output.

D_{OUT} (Pin 4): Output of the Shift Register. Becomes valid on the rising edge of the serial clock and swings from GND to V_{CC}.

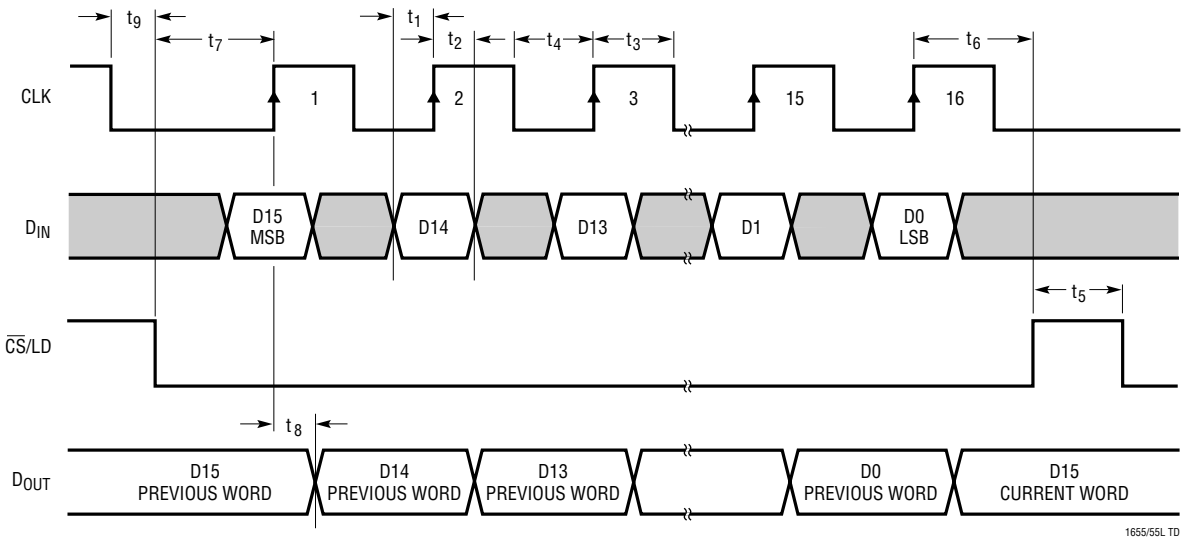
GND (Pin 5): Ground.

REF (Pin 6): Reference. Output of the internal reference is 2.048V (LTC1655), 1.25V (LTC1655L). There is a gain of two from this pin to the output. The reference can be overdriven from 2.2V to V_{CC}/2 (LTC1655) and 1.3V to V_{CC}/2 (LTC1655L). When tied to V_{CC}/2, the output will swing from GND to V_{CC}. The output can only swing to within its offset specification of V_{CC} (see Applications Information).

V_{OUT} (Pin 7): Deglitched Rail-to-Rail Voltage Output. V_{OUT} clears to 0V on power-up.

V_{CC} (Pin 8): Positive Supply Input. $4.5V \leq V_{CC} \leq 5.5V$ (LTC1655), $2.7V \leq V_{CC} \leq 5.5V$ (LTC1655L). Requires a 0.1µF bypass capacitor to ground.

TIMING DIAGRAM



DEFINITIONS

Differential Nonlinearity (DNL): The difference between the measured change and the ideal 1LSB change for any two adjacent codes. The DNL error between any two codes is calculated as follows:

$$DNL = (\Delta V_{OUT} - LSB)/LSB$$

Where ΔV_{OUT} is the measured voltage difference between two adjacent codes.

Digital Feedthrough: The glitch that appears at the analog output caused by AC coupling from the digital inputs when they change state. The area of the glitch is specified in (nV)(sec).

Full-Scale Error (FSE): The deviation of the actual full-scale voltage from ideal. FSE includes the effects of offset and gain errors (see Applications Information).

Gain Error (GE): The difference between the full-scale output of a DAC from its ideal full-scale value after offset error has been adjusted.

Integral Nonlinearity (INL): The deviation from a straight line passing through the endpoints of the DAC transfer curve (Endpoint INL). Because the output cannot go below zero, the linearity is measured between full scale and the lowest code that guarantees the output will be greater than zero. The INL error at a given input code is calculated as follows:

$$INL = [V_{OUT} - V_{OS} - (V_{FS} - V_{OS})(code/65535)]/LSB$$

Where V_{OUT} is the output voltage of the DAC measured at the given input code.

Least Significant Bit (LSB): The ideal voltage difference between two successive codes.

$$LSB = 2V_{REF}/65536$$

Resolution (n): Defines the number of DAC output states (2^n) that divide the full-scale range. Resolution does not imply linearity.

Voltage Offset Error (V_{OS}): Nominally, the voltage at the output when the DAC is loaded with all zeros. A single supply DAC can have a true negative offset, but the output cannot go below zero (see Applications Information).

For this reason, single supply DAC offset is measured at the lowest code that guarantees the output will be greater than zero.

OPERATION

Serial Interface

The data on the D_{IN} input is loaded into the shift register on the rising edge of the clock. The MSB is loaded first. The DAC register loads the data from the shift register when $\overline{CS}$/LD is pulled high. The clock is disabled internally when $\overline{CS}$/LD is high. Note: CLK must be low before $\overline{CS}$/LD is pulled low to avoid an extra internal clock pulse. The input word must be 16 bits wide.

The buffered output of the 16-bit shift register is available on the D_{OUT} pin which swings from GND to V_{CC}.

Multiple LTC1655s/LTC1655Ls may be daisy-chained together by connecting the D_{OUT} pin to the D_{IN} pin of the next chip while the clock and $\overline{CS}$/LD signals remain common to all chips in the daisy chain. The serial data is clocked to all of the chips, then the $\overline{CS}$/LD signal is pulled high to update all of them simultaneously. The shift register and DAC register are cleared to all 0s on power-up.

Voltage Output

The LTC1655/LTC1655L rail-to-rail buffered output can source or sink 5mA over the entire operating temperature range while pulling to within 600mV of the positive supply voltage or ground. The output stage is equipped with a deglitcher that gives a midscale glitch of 12nV-s. At power-up, the output clears to 0V.

The output swings to within a few millivolts of either supply rail when unloaded and has an equivalent output resistance of 40Ω (70Ω for the LTC1655L) when driving a load to the rails. The output can drive 1000pF without going into oscillation.

APPLICATIONS INFORMATION

Rail-to-Rail Output Considerations

In any rail-to-rail DAC, the output swing is limited to voltages within the supply range.

If the DAC offset is negative, the output for the lowest codes limits at 0V as shown in Figure 1b.

Similarly, limiting can occur near full-scale when the REF pin is tied to $V_{CC}/2$. If $V_{REF} = V_{CC}/2$ and the DAC full-scale error (FSE) is positive, the output for the highest codes limits at V_{CC} as shown in Figure 1c. No full-scale limiting can occur if V_{REF} is less than (V_{CC} – FSE)/2.

Offset and linearity are defined and tested over the region of the DAC transfer function where no output limiting can occur.

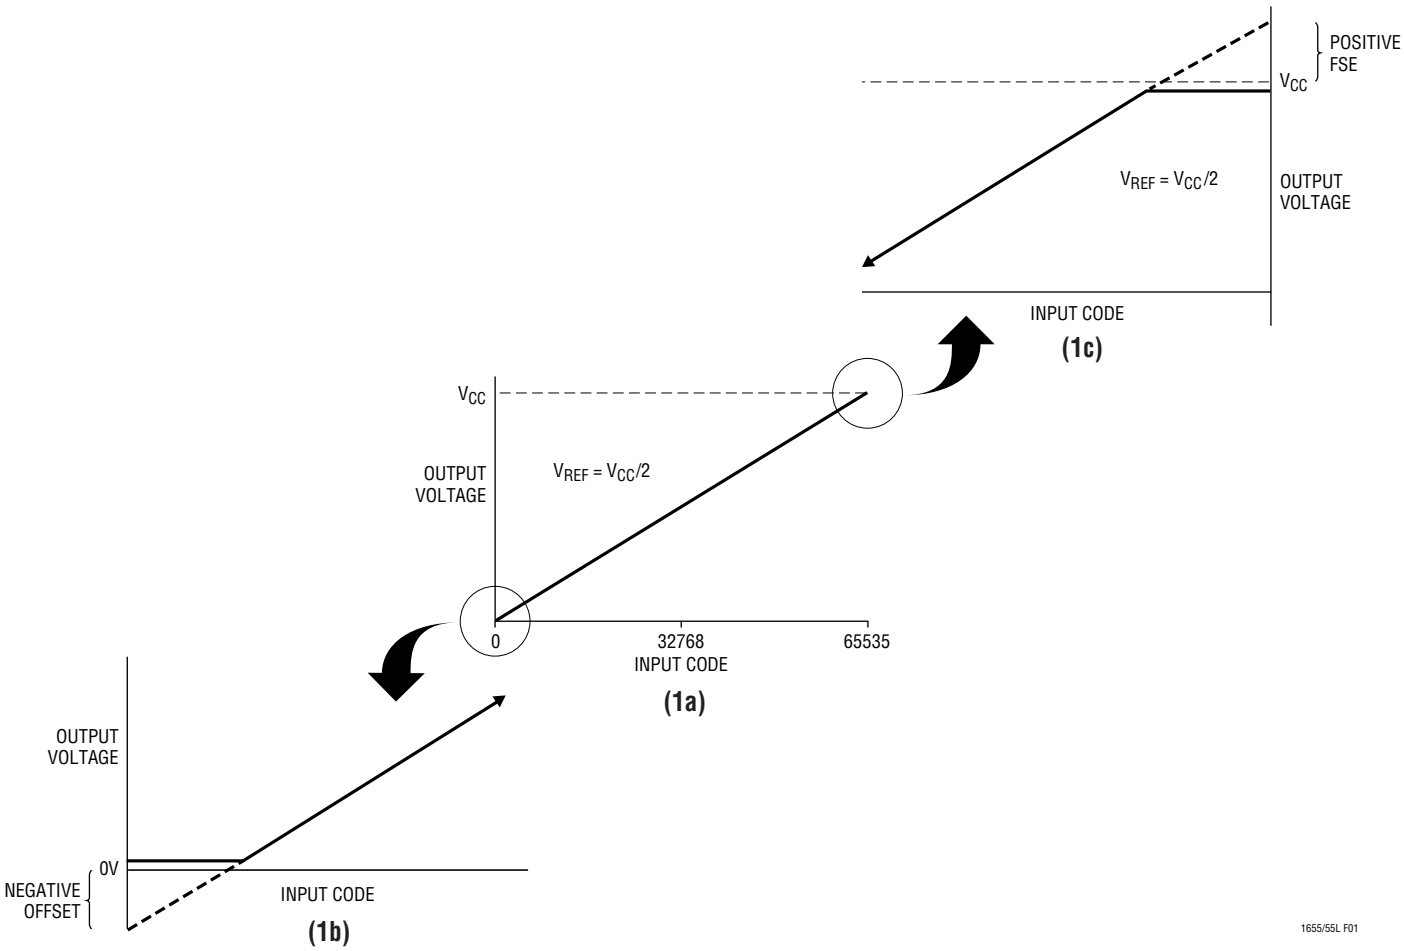


Figure 1. Effects of Rail-to-Rail Operation On a DAC Transfer Curve. (a) Overall Transfer Function (b) Effect of Negative Offset for Codes Near Zero Scale (c) Effect of Positive Full-Scale Error for Input Codes Near Full Scale When $V_{REF} = V_{CC}/2$

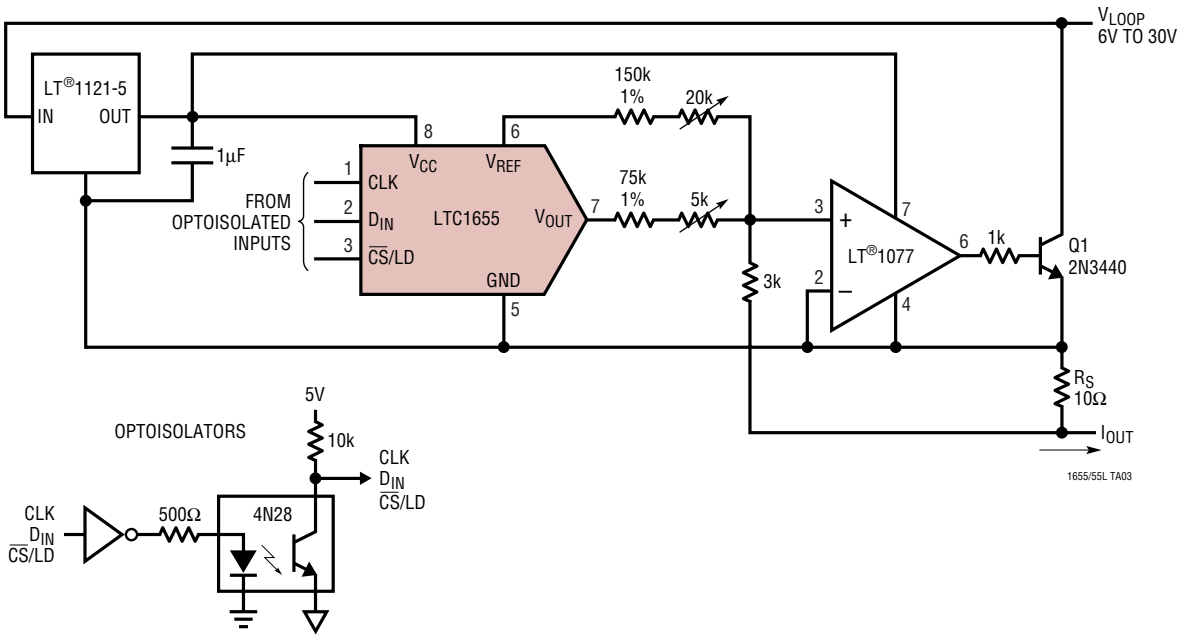
TYPICAL APPLICATIONS

This circuit shows how to use an LTC1655 to make an optoisolated digitally controlled 4mA to 20mA process controller. The controller circuitry, including the optoisolation, is powered by the loop voltage that can have a wide range of 6V to 30V. The 2.048V reference output of the LTC1655 is used for the 4mA offset current and V_{OUT} is used for the digitally controlled 0mA to 16mA current. R_S is a sense resistor and the op amp modulates the transistor Q1 to provide the 4mA to 20mA current through this resistor. The potentiometers allow for offset and full-scale adjustment. The control circuitry dissipates well under the 4mA budget at zero scale.

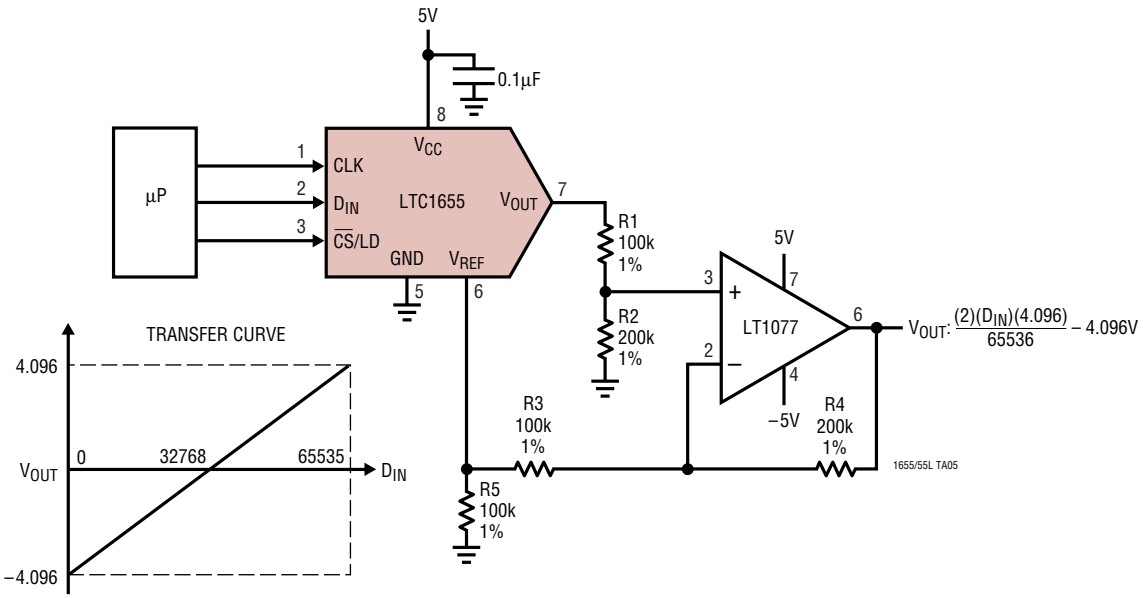
An Isolated 4mA to 20mA Process Controller



TYPICAL APPLICATIONS

This circuit shows how to make a bipolar output 16-bit DAC with a wide output swing using an LTC1655 and an LT1077. R1 and R2 resistively divide down the LTC1655 output and an offset is summed in using the LTC1655 onboard 2.048V reference and R3 and R4. R5 ensures that the onboard reference is always sourcing current and never has to sink any current even when V_{OUT} is at full scale. The LT1077 output will have a wide bipolar output swing of –4.096V to 4.096V as shown in the figure below. With this output swing 1LSB = 125µV.

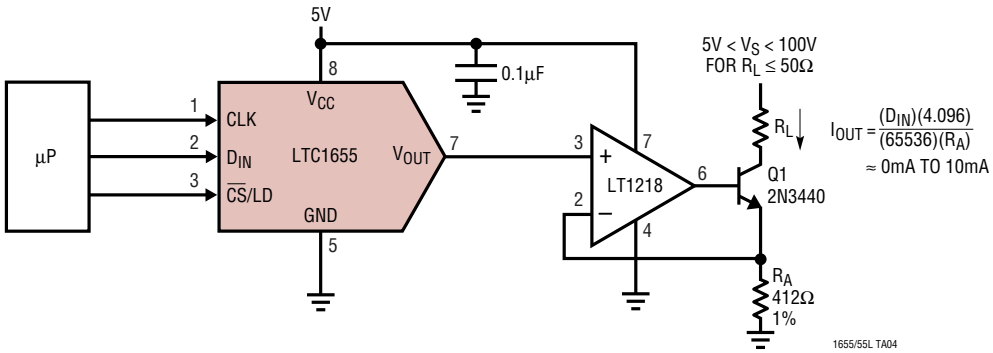
A Wide Swing, Bipolar Output 16-Bit DAC



TYPICAL APPLICATIONS

This circuit shows a digitally programmable current source from an external voltage source using an external op amp, an LT1218 and an NPN transistor (2N3440). Any digital word from 0 to 65535 is loaded into the LTC1655 and its output correspondingly swings from 0V to 4.096V. This voltage will be forced across the resistor R_A. If R_A is chosen to be 412Ω, the output current will range from 0mA at zero scale to 10mA at full scale. The minimum voltage for V_S is determined by the load resistor R_L and Q1's V_{CESAT} voltage. With a load resistor of 50Ω, the voltage source can be 5V.

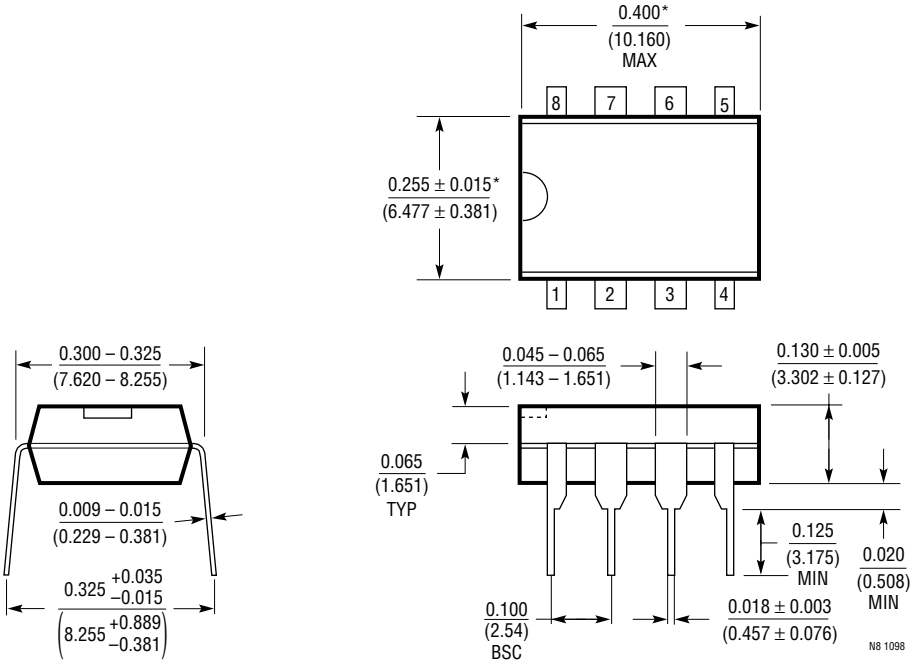
Digitally Programmable Current Source



PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

N8 Package
8-Lead PDIP (Narrow 0.300)
(LTC DWG # 05-08-1510)

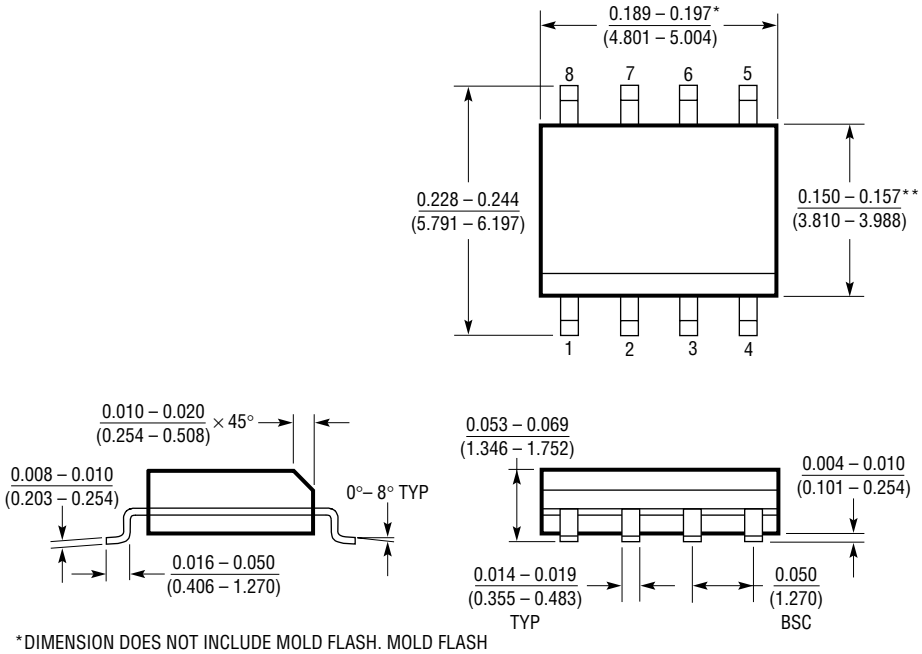


*THESE DIMENSIONS DO NOT INCLUDE MOLD FLASH OR PROTRUSIONS.
MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.010 INCH (0.254mm)

PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

S8 Package
8-Lead Plastic Small Outline (Narrow 0.150)
(LTC DWG # 05-08-1610)



*DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE

**DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE

S08 1298

TYPICAL APPLICATION

This circuit shows how to measure negative offset. Since LTC1655/LTC1655L operate on a single supply, if its offset is negative, the output for code 0 limits to 0V. To measure this negative offset, a negative supply is needed. Connect resistor R1 as shown in the figure below. The output voltage is the offset when code 0 is loaded in.

Negative Offset Measurement
