

MAX3535E/MXL1535E

+3V to +5V, 2500V_{RMS} Isolated RS-485/RS-422 Transceivers with ±15kV ESD Protection

ABSOLUTE MAXIMUM RATINGS

Logic Side—All Voltages Referenced to GND1.

V_{CC1} -0.3V to +6V

$\overline{RE}$, DE, DI -0.3V to +6V

RO1, ST1, ST2 -0.3V to (V_{CC1} + 0.3V)

Isolated Side—All Voltages Referenced to GND2.

V_{CC2} -0.3V to +8V

SLO -0.3V to (V_{CC2} + 0.3V)

A, B ±14V

RO2 -0.3V to the lower of (V_{CC2} + 0.3V) and +3.4V

Y, Z -8V to +13V

Digital Outputs Maximum Current

RO1, RO2 ±20mA

Y, Z Maximum Current Short-Circuit Protected

ST1, ST2 Maximum Current ±300mA

Continuous Power Dissipation (T_A = +70°C)

28-Pin Wide SO

(derate 9.5mW/°C above +70°C) 750mW

Operating Temperature Range

MXL1535ECWI, MAX3535ECWI 0°C to +70°C

MXL1535EEWI, MAX3535EEWI -40°C to +85°C

Junction Temperature +150°C

Storage Temperature Range -65°C to +150°C

Lead Temperature (soldering, 10s) +300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DC ELECTRICAL CHARACTERISTICS TABLE (MAX3535E)

(V_{CC1} = +3.0V to +5.5V, V_{CC2} = +3.13V to +7.5V, T_A = -40°C to +85°C, unless otherwise noted. Typical values are at V_{CC1} = +3.3V, V_{CC2} = +5V, T_A = +25°C.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
LOGIC-SIDE SUPPLY (V_{CC1}, GND1)						
Logic-Side Supply Voltage	V _{CC1}		3.0		5.5	V
Logic-Side Supply Current	I _{CC1}	Transformer not driven, ST1 and ST2 unconnected, $\overline{RE}$ = low, DE = high, f _{DATA} = 0, RO1 = no load		5.9	13	mA
V _{CC1} Undervoltage-Lockout Falling Trip	V _{UVL1}		2.53	2.69	2.85	V
V _{CC1} Undervoltage-Lockout Rising Trip	V _{UVH1}		2.63	2.80	2.97	V
LOGIC INPUTS (DI, DE, $\overline{RE}$)						
Input High Voltage, DE, DI, $\overline{RE}$	V _{IH}	V _{IH} is measured with respect to GND1	2.0			V
Input Low Voltage, DE, DI, $\overline{RE}$	V _{IL}	V _{IL} is measured with respect to GND1			0.8	V
Logic-Side Input Current, DE, DI	I _{INC}				±2	μA
LOGIC OUTPUTS (RO1, $\overline{RE}$)						
Receiver-Output High Voltage (RO1)	V _{RO1H}	I _{SOURCE} = 4mA, V _{CC1} = +4.5V	3.7			V
		I _{SOURCE} = 4mA, V _{CC1} = +3V	2.4

		-40°C to +85°C			57	
ESD Protection		Human Body Model (A, B, Y, Z)		±15		kV

Note 1: Receiver inputs are 96kΩ minimum resistance, which is 1/8 unit load.

Note 2: 60s test result is guaranteed by correlation from 1s result.

Note 3: V_{ISO} is the voltage difference between GND1 and GND2.

Note 4: The maximum data rate is specified using the maximum jitter value according to the formula: data rate = 1 / (4t_J). See the Skew section for more information.

Note 5: Initial startup time is the time for communication to recover after a fault condition. Internal communication timeout fault time is the time before a fault is indicated on RE, after internal communication has stopped.

Note 6: Bd = 2 bits.

Pin Description

PIN	NAME	ISOLATION SIDE	FUNCTION
1	V _{CC1}	Logic	Logic-Side/Transformer-Driver Power Input. Bypass V _{CC1} to GND1 with 10 μ F and 0.1 μ F capacitors.
2	ST1	Logic	Transformer-Driver Phase 1 Power Output. Connect ST1 to isolation-transformer primary to send power to isolation side of barrier.
3	ST2	Logic	Transformer-Driver Phase 2 Power Output. Connect ST2 to isolation-transformer primary to send power to isolation side of barrier.
4	GND1	Logic	Logic-Side Ground. For isolated operation do not connect to GND2.
5–10, 19–24	—	—	Removed from Package
11	GND2	Isolated	Isolation-Side Ground. For isolated operation do not connect to GND1.
12	Z	Isolated	RS-485/RS-422 Inverting Driver Output. Output floats when DE is low or in a barrier fault event. (See the <i>Detailed Description</i> section for more information.)
13	Y	Isolated	RS-485/RS-422 Noninverting Driver Output. Output floats when DE is low or in a barrier fault event. (See the <i>Detailed Description</i> section for more information.)
14	V _{CC2}	Isolated	Isolated-Side Power Input. Connect V _{CC2} to the rectified output of transformer secondary. Bypass V _{CC2} to GND2 with 10 μ F and 0.1 μ F capacitors.
15	B	Isolated	RS-485/RS-422 Differential-Receiver Inverting Input
16	A	Isolated	RS-485/RS-422 Differential-Receiver Noninverting Input
17	RO2	Isolated	Isolated-Side Receiver Output. RO2 is always enabled. RO2 goes high if A - B > -10mV. RO2 goes low if A - B < -200mV. Fail-safe circuitry causes RO2 to go high when A and B float or are shorted.
18	$\overline{\text{SLO}}$	Isolated	Driver Slew-Rate Control Logic Input. Connect $\overline{\text{SLO}}$ to GND2 for data rates up to 400kbps. Connect $\overline{\text{SLO}}$ to V _{CC2} or leave floating for high data rates.
25	DI	Logic	Driver Input. Pull DI low (high) to force driver output Y low (high) and driver output Z high (low).
26	DE	Logic	Driver-Enable Input. The driver outputs are enabled and follow the driver input (DI) when DE is high. When DE is floated, the driver is disabled. DE does not affect whether the receiver is on or off.
27	$\overline{\text{RE}}$	Logic	Receiver-Output Enable and Fault Current Output. The receiver output (RO1) is enabled and follows the differential-receiver inputs, A and B, when $\overline{\text{RE}}$ is low, otherwise RO1 floats. $\overline{\text{RE}}$ does not affect RO2 and does not disable the driver. The asserted fault output is a pullup current, otherwise $\overline{\text{RE}}$ shows a pulldown current.
28	RO1	Logic	Receiver Output. RO1 is enabled when $\overline{\text{RE}}$ is low. RO1 goes high if A - B > -10mV. RO1 goes low if A - B < -200mV. Fail-safe circuitry causes RO1 to go high when A and B float or are shorted.

MAX3535E/MXL1535E

+3V to +5V, 2500V_{RMS} Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

Test Circuits

Figure 1. Driver DC Test Load

Figure 3. Driver Timing Test Load

Figure 2. Driver Timing Test Circuit

Figure 4. Receiver Timing Test Load

Figure 5. Self-Oscillating Configuration

+3V to +5V, 2500VRMS Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

The diagram shows three signals: DI (Data Input), Z (Output Data), and Y (Output Enable). The DI signal is a square wave with a high level of 1.5V. The Z signal is a square wave that is high when Y is high and low when Y is low. The Y signal is a square wave that is high during the data transfer cycle and low otherwise. The output data Z is shown with a setup time $t_{R} < 10\text{ns}$ and a hold time $t_{F} < 10\text{ns}$ relative to the Y signal. The output data Z is also shown with a setup time t_{DD} and a hold time t_{DD} relative to the Y signal. The output data Z is shown with a setup time t_{DD} and a hold time t_{DD} relative to the Y signal. The output data Z is shown with a setup time t_{DD} and a hold time t_{DD} relative to the Y signal.

[illegible]

The diagram illustrates the timing characteristics of the 74VHC00 inverter. It shows the input signal (DE) and the output signal (Y, Z) for two cases: 'OUTPUT NORMALLY LOW' and 'OUTPUT NORMALLY HIGH'.

Input Signal (DE): A square wave with a high level of 1.5V. The rise time t_R and fall time t_F are both less than 10ns.

Output Signal (Y, Z): The output is shown for two states:

- OUTPUT NORMALLY LOW:** The output voltage transitions from V_{DOL} to $V_{DOH}/2$ and then to V_{DOH} . The propagation delay t_{pZL} is measured from the input crossing V_{DOL} to the output crossing $V_{DOH}/2$.
- OUTPUT NORMALLY HIGH:** The output voltage transitions from V_{DOH} to $V_{DOH}/2$ and then to V_{DOL} . The propagation delay t_{pZH} is measured from the input crossing V_{DOL} to the output crossing $V_{DOH}/2$.

Timing Parameters:

- t_{pZL} : Propagation delay from input low to output low.
- t_{pZH} : Propagation delay from input low to output high.
- t_{pLZ} : Propagation delay from input high to output low.
- t_{pHZ} : Propagation delay from input high to output high.
- $2 \times t_j$: Total delay from input transition to output transition.
- t_j : Intrinsic delay of the output stage.

The diagram shows the timing characteristics of the 74VHC00. The RE input signal is a square wave with a period $t_R < 10\text{ns}$ and a high level of 1.5V. The RO1 output signal is normally low, with a propagation delay t_{PL} from the RE input transition. The VO1 output signal is normally high, with a propagation delay t_{PH} from the RE input transition. The output voltage levels are V_{RO1L} and V_{RO1H} , with $V_{RO1H} \geq 0.5V$ and $V_{RO1L} \leq 0.5V$. The setup and hold times t_{SU} and t_{HU} are indicated for the RE input signal.

MAX3535E/MXL1535E

+3V to +5V, 2500V_{RMS} Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

Detailed Description

The MAX3535E/MXL1535E isolated RS-485/RS-422 full-duplex transceivers provide 2500V_{RMS} of galvanic isolation between the RS-485/RS-422 isolation side and the processor or logic side. These devices allow fast, 1000kbps communication across an isolation barrier even when the common-mode voltages (i.e., the ground potentials) on either side of the barrier are subject to large differences. The isolation barrier consists of two parts. The first part is a capacitive isolation barrier (integrated high-voltage capacitors) that allows data transmission between the logic side and the RS-485/RS-422 isolation side. Data is sampled and encoded before it is transmitted across the isolation barrier introducing sampling jitter and further delay into the communication system.

The second part of the isolation barrier consists of an external transformer with the required primary-to-secondary isolation, allowing the transmission of operating power from the logic side across the isolation barrier to the isolation side. Connect the primary of the external transformer to the MAX3535E/MXL1535E's 420kHz transformer driver outputs ST1 and ST2. Since the MXL1535E and the MAX3535E operate with different supply-voltage requirements at their respective isolated and logic sides, different isolation transformers must be used with each device (see the *Transformer Selection* section). The only external components needed to complete the system are the isolation transformer, two diodes, and two low-voltage, 10 μ F decoupling capacitors (see the *Typical Application Circuit*).

The MAX3535E/MXL1535E include one differential driver, one receiver, and internal circuitry to send the RS-485 signals and logic signals across the isolation barrier (including the isolation capacitors). The MAX3535E/MXL1535E receivers are 1/8 unit load, allowing up to 256 devices on a single bus.

The MAX3535E/MXL1535E feature fail-safe circuitry ensuring the receiver output maintains a logic-high state when the receiver inputs are open or shorted, or when connected to a terminated transmission line with all drivers disabled (see the *Fail Safe* section).

The MAX3535E/MXL1535E feature driver slew-rate select that minimizes electromagnetic interference (EMI) and reduces reflections caused by improperly terminated cables at data rates below 400kbps. The

driver outputs are short-circuit protected for sourcing or sinking current and have overvoltage protection. Other features include hot-swap capability, which holds the driver off if the driver logic signals are floated after power is applied. The MAX3535E/MXL1535E have error-detection circuitry that alerts the processor when there is a fault and disables the driver until the fault is removed.

Fail Safe

The MAX3535E/MXL1535E guarantee a logic-high receiver output when the receiver inputs are shorted or open, or when connected to a terminated transmission line with all drivers disabled. The receiver threshold is fixed between -10mV and -200mV. If the differential receiver input voltage (A - B) is greater than or equal to -10mV, RO1 is logic-high (Table 2). In the case of a terminated bus with all transmitters disabled, the receiver's differential input voltage is pulled to zero by the termination. Due to the receiver thresholds of the MAX3535E/MXL1535E, this results in a logic-high at RO1 with a 10mV minimum noise margin.

Driver Output Protection

Two mechanisms prevent excessive output current and power dissipation caused by faults or by bus contention. The first, a foldback current limit on the output stage, provides immediate protection against short circuits over the entire common-mode voltage range. The second, a thermal-shutdown circuit, forces the driver outputs into a high-impedance state if the die temperature exceeds +150°C.

Monitoring Faults on $\overline{RE}$

$\overline{RE}$ functions as both an input and an output. As an input, $\overline{RE}$ controls the receiver output enable (RO1). As an output, $\overline{RE}$ is used to indicate when there are faults associated with the operation of the part. This dual functionality is made possible by using an output driver stage that can easily be overdriven by most logic gates. When an external gate is not actively driving $\overline{RE}$, it is driven either high using a 100 μ A internal pullup current (fault present), or low using a 60 μ A internal pull-down current (no fault). When using $\overline{RE}$ to control the receiver-enable output function, be sure to drive it using a gate that has enough sink and source capability to overcome the internal drive.

MAX3535E/MXL1535E

+3V to +5V, 2500VRMS Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

When not actively driving $\overline{\text{RE}}$, it functions as the fault indicator (Table 3). A low on $\overline{\text{RE}}$ indicates the part is functioning properly, while a high indicates a fault is present. The four causes of a fault indication are:

- 1) The voltage on VCC1 is below its undervoltage-lock-out threshold (2.69V nominal)
- 2) The voltage on VCC2 is below its undervoltage-lock-out threshold (2.80V nominal)
- 3) There is a problem that prevents the MAX3535E/MXL1535E from communicating across its isolation barrier
- 4) The die temperature exceeds $+150^\circ\text{C}$ nominally, causing the part to go into thermal shutdown

When a fault occurs, RO1 is switched to a logic-high state if $\overline{\text{RE}}$ is low (Table 3). Open-circuit or short-circuit conditions on the receiver inputs do not generate fault conditions; however, any such condition also puts RO1 in a logic-high state (see the *Fail Safe* section).

Read $\overline{\text{RE}}$ for fault conditions by using a bidirectional microcontroller I/O line or a tri-stated buffer as shown in Figure 10. When using a tri-stated buffer, enable the driver whenever the voltage on $\overline{\text{RE}}$ needs to be forced to a logic-high or logic-low. To read $\overline{\text{RE}}$ for a fault condition, disable the driver.

Slew-Rate Control Logic

The $\overline{\text{SLO}}$ input selects between a fast and a slow slew rate for the driver outputs. Connecting $\overline{\text{SLO}}$ to GND2 selects the slow slew-rate option that minimizes EMI and reduces reflections caused by improperly terminated cables at data rates up to 400kbps. This occurs because lowering the slew rate decreases the rise and fall times for the signal at the driver outputs, drastically reducing the high-frequency components and harmonics at the output. Floating $\overline{\text{SLO}}$ or connecting it to VCC2 selects the fast slew rate, which allows high-speed operation.

Figure 13. Transformer Driver Output Stage

Transformer Selection

The MXL1535E is a pin-for-pin compatible upgrade of the LTC1535, making any transformer designed for that device suitable for the MXL1535E (see Table 4). These transformers all have a turns ratio of about 1:1.3CT.

The MAX3535E can operate with any of the transformers listed in Table 4, in addition to smaller, thinner transformers designed for the MAX845 and MAX253. The 420kHz transformer driver operates with single primary and center-tapped secondary transformers. When selecting a transformer, do not exceed its ET product, the product of the maximum primary voltage and half the highest period of oscillation (lowest oscillating frequency). This ensures that the transformer does not enter saturation. Calculate the minimum ET product for the transformer primary as:

$$ET = V_{MAX} / (2 \times f_{MIN})$$

where, V_{MAX} is the worst-case maximum supply voltage, and f_{MIN} is the minimum frequency at that supply voltage. Using +5.5V and 290kHz gives a required minimum ET

MAX3535E/MXL1535E

+3V to +5V, 2500VRMS Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

product of 9.5V- μs . The commercially available transformers for the MAX845 listed in Table 5 meet that requirement. In most cases, use half of the center-tapped primary winding with the MAX3535E and leave the other end of the primary floating. Most of the transformers in Table 5 are 1:1:1 or 1:1:1:1 turns ratio.

For +3.3V operation (+3.6V maximum) the required primary ET product is 6.2V- μs . All of the previously mentioned transformers meet this requirement. Table 6 lists some other transformers with step-up turns ratios specifically tailored for +3.3V operation. Most of the transformers in Table 6 are 1:1:1.3:1.3.

By using a HALO TGM-010 or Midcom 95061 transformer, it becomes possible to build a complete isolated RS-485/RS-422 transceiver with a maximum thickness

less than 0.1in. To minimize power consumption, select the turns ratio of the transformer to produce the minimum DC voltage required at VCC2 (+3.13V) under worst-case, high-temperature, low-VCC1, and full-load conditions. For light loads on the isolated side, ensure that the voltage at VCC2 does not exceed +7.5V. For example, the CTX01-14659 transformer results in 85mA (typ) VCC1 supply current with full load on the RS-485 driver. Using a TGM250 1:1:1 transformer lowers the VCC1 supply current to 65mA (typ), while maintaining good margin on the VCC2 supply. A slight step-down transformer can result in extra power savings in some situations. A custom wound sample transformer with 23 primary turns and 20:20 secondary turns on a Ferronics 11-050B core operates well with a VCC1 supply current of 51mA (typ).

$\pm 15\text{kV}$ ESD Protection

As with all Maxim devices, ESD-protection structures are incorporated on all pins to protect against electrostatic discharges encountered during handling and assembly. The driver outputs and receiver inputs have extra protection against static electricity. Maxim's engineers have developed state-of-the-art structures to protect these pins against ESD of $\pm 15\text{kV}$ without damage. The ESD structures withstand high ESD in all states. After an ESD event, the MAX3535E/MXL1535E keep working without latchup. ESD protection can be tested in various ways. The transmitter outputs and receiver inputs of this product family are characterized for protection to $\pm 15\text{kV}$ using the Human Body Model.

ESD Test Conditions

The $\pm 15\text{kV}$ ESD test specifications apply only to the A, B, Y, and Z I/O pins. The test surge is referenced to GND2. All remaining pins are $\pm 2\text{kV}$ ESD protected.

Human Body Model

Figure 14 shows the Human Body Model, and Figure 15 shows the current waveform it generates when dis-

Figure 14. Human Body ESD Test Model

charged into low impedance. This model consists of a 100pF capacitor charged to the ESD voltage of interest, which is then discharged into the test device through a 1.5kΩ resistor.

MAX3535E/MXL1535E

+3V to +5V, 2500VRMS Isolated RS-485/RS-422 Transceivers with $\pm 15\text{kV}$ ESD Protection

Figure 15. Human Body Current Waveform

Machine Model

The Machine Model for ESD tests all pins using a 200pF storage capacitor and zero discharge resistance. Its objective is to simulate the stress caused by contact that occurs with handling and assembly during manufacturing. All pins require this protection during manufacturing, not just inputs and outputs. Therefore, after PC board assembly, the Machine Model is less relevant to I/O ports.

Skew

The self-oscillation circuit shown in Figure 5 is an excellent way to get an approximate measure of the speed of the MAX3535E/MXL1535E. An oscillation frequency of 250kHz in this configuration implies a data rate of at least 500kbps for the receiver and transmitter combined. In practice, data can usually be sent and received at a considerably higher data rate, normally limited by the allowable jitter and data skew. If the system can tolerate a 25% data skew, (the difference between t_{PLH1} and t_{PHL1}), the 285ns maximum jitter specification implies a data rate of 877kbps. Lower data rates result in less distortion and jitter (Figure 16).

Figure 16. Data Skew vs. Data Rate Graph

Higher rates are possible but with more distortion and jitter. The data rate should always be limited below 1.75Mbps for both receiver and driver to avoid interference with the internal barrier communication.

Layout Considerations

The MAX3535E/MXL1535E pin configurations enable optimal PC board layout by minimizing interconnection lengths and crossovers:

- For maximum isolation, the isolation barrier should not be breached except by the MAX3535E/MXL1535E and the transformer. Connections and components from one side of the barrier should not be located near those of the other side of barrier.
- A shield trace connected to the ground on each side of the barrier can help intercept capacitive currents that might otherwise couple into the DI and $\overline{\text{SLO}}$ inputs. In a double-sided or multilayer board, these shield traces should be present on all conductor layers.
- Try to maximize the width of the isolation barrier wherever possible. A clear space of at least 0.25in between GND1 and GND2 is recommended.
