PIN DESCRIPTIONS

Pin Descriptions

NAME	32-QFN PIN#	TYPE	DESCRIPTION
DATA BUS INTERFACE (CMOS/TTL Voltage Levels)			
A2 A1 A0	18 19 20	I	Address bus lines [2:0]. These 3 address lines select one of the internal registers in the UART during a data bus transaction.
D7 D6 D5 D4 D3 D2 D1 D0	6 5 3 32 31 30 29 28	I/O	Data bus lines [7:0] (bidirectional).
IOR# (NC)	14	I	When I/M# pin is HIGH, the Intel bus interface is selected and this input becomes read strobe (active LOW). The falling edge instigates an internal read cycle and retrieves the data byte from an internal register pointed by the address lines [A2:A0], puts the data byte on the data bus to allow the host processor to read it on the rising edge. When I/M# pin is LOW, the Motorola bus interface is selected and this input is not used.
IOW# (R/W#)	11	I	When I/M# pin is HIGH, it selects Intel bus interface and this input becomes write strobe (active LOW). The falling edge instigates the internal write cycle and the rising edge transfers the data byte on the data bus to an internal register pointed by the address lines. When I/M# pin is LOW, the Motorola bus interface is selected and this input becomes read (HIGH) and write (LOW) signal.
CS#	7	I	This input is chip select (active LOW) to enable the device.
INT (IRQ#)	21	O (OD)	When I/M# pin is HIGH, it selects Intel bus interface and this output become the active HIGH device interrupt output. This output is enabled through the software setting of MCR[3]: set to the active mode when MCR[3] is set to a logic 1, and set to the three state mode when MCR[3] is set to a logic 0. See MCR[3]. When I/M# pin is LOW, it selects Motorola bus interface and this output becomes the active LOW, open-drain interrupt output. An external pull-up resistor is required for proper operation. MCR[3] must be set to a logic 0 for proper operation of the interrupt.
MODEM OR SERIAL I/O INTERFACE (EIA-232/RS-232 Voltage Levels)			
TXD	8	O	UART Transmit Data. The TX signal will be LOW (< -5V) during reset or idle (no data).
RXD	1	I	UART Receive Data. The RX data input must idle LOW (< -3V).
ANCILLARY SIGNALS (CMOS/TTL Voltage Levels)			
XTAL1	9	I	Crystal or external clock input. This input is not 5V tolerant.
XTAL2	10	O	Crystal or buffered clock output. This output may be use to drive a clock buffer which can drive other device(s).
ACP	12	I	Autosleep for Charge Pump (active HIGH). When this pin is HIGH, the charge pump is shut off if the L200 is already in partial sleep mode, i.e. the crystal oscillator is stopped.

Pin Descriptions

NAME	32-QFN PIN#	TYPE	DESCRIPTION
I/M#	2	I	Intel or Motorola Bus Select. When I/M# pin is HIGH, 16 or Intel Mode, the device will operate in the Intel bus type of interface. When I/M# pin is LOW, 68 or Motorola mode, the device will operate in the Motorola bus type of interface.
RESET (RESET#)	23	I	When I/M# pin is HIGH for Intel bus interface, this input becomes RESET (active high). When I/M# pin is LOW for Motorola bus interface, this input becomes RESET# (active low). A 40 ns minimum active pulse on this pin will reset the internal registers and all outputs of the UART. The UART transmitter output will be held HIGH, the receiver input will be ignored and outputs are reset during reset period (see **Table 11**).
C2+ C2-	15 16	-	Charge pump capacitors. As shown in **Figure 1**, a 0.1 uF capacitor should be placed between these 2 pins.
C1+ C1-	24 25	-	Charge pump capacitors. As shown in **Figure 1**, a 0.1 uF capacitor should be placed between these 2 pins.
VREF+	26	Pwr	+5.0V generated by the charge pump.
VREF-	17	Pwr	-5.0V generated by the charge pump.
VCC	27	Pwr	3.0V to 5.5V power supply. All CMOS/TTL input pins, except XTAL1, are 5V tolerant.
GND	13	Pwr	Power supply common, ground.
GND	-	Pwr	The center pad on the backside of the 32-QFN package is metallic and is not electrically connected to anything inside the device. It must be soldered on to the PCB and may be optionally connected to GND on the PCB. The thermal pad size on the PCB should be the approximate size of this center pad and should be solder mask defined. The solder mask opening should be at least 0.0025" inwards from the edge of the PCB thermal pad.
NC	-	-	No Connect. Note that in Motorola mode, the IOR# pin also becomes an NC pin.

NOTE: *Pin type: I=Input, O=Output, I/O= Input/output, OD=Output Open Drain. For CMOS/TTL Voltage levels, 'LOW' indicates a voltage in the range 0V to VIL and 'HIGH" indicates a voltage in the range VIH to VCC. For RS-232 input voltage levels, 'LOW' is any voltage < -3V and 'HIGH' is any voltage > 3V. For RS-232 output voltage levels, 'LOW' is any voltage < -5V and 'HIGH' is any voltage > 5V.*

1.0 PRODUCT DESCRIPTION

The XR19L200 interface converter consists of a full-functional UART with 16 bytes of transmit and receive FIFO, a charge pump, two RS-232 drivers, two RS-232 receivers, and a sleep mode circuitry. It operates from a single +3V to 5.5V supply at 250Kbps data rate, while meeting all EIA RS-232F specifications. Its feature set is fully compatible to the XR16L580 device. Unlike the XR16L580, the modem signals are not CMOS/TTL level, but conform to EIA/TIA 232 or RS-232 voltage levels. The configuration registers set is 16550 UART compatible for control, status and data transfer. Also, the L200 has 16-bytes of transmit and receive FIFOs, automatic Xon/Xoff and special character software flow control, transmit and receive FIFO trigger levels, and a programmable baud rate generator with a prescaler of divide by 1 or 4. Additionally, the L200 includes the ACP pin which the user can shut down the charge pump for the RS-232 drivers when the L200 is already in sleep mode. The L200 is fabricated using an advanced CMOS process.

Enhanced Features

The L200 UART provides a solution that supports 16 bytes of transmit and receive FIFO memory. The L200 is designed to work with low supply voltage and high performance data communication systems that require fast data processing time. Increased performance is realized in the L200 by the transmit and receive FIFOs, FIFO trigger level controls and automatic flow control mechanism. This allows the external processor to handle more networking tasks within a given time. This increases the service interval giving the external CPU additional time for other applications and reducing the overall UART interrupt servicing time.

Intel or Motorola Data Bus Interface

The L200 provides a host interface that supports Intel or Motorola microprocessor (CPU) data bus interface. The Intel bus compatible interface allows direct interconnect to Intel compatible type of CPUs using IOR#, IOW# and CS# inputs for data bus operation. The Motorola bus compatible interface instead uses the R/W# and CS# signals for data bus transactions. See pin description section for details on all the control signals. The Intel and Motorola bus interface selection is made through the pin, I/M#.

Data Rate

The L200 is capable of operation up to 250Kbps data rate using the 16X internal sampling clock rate. The UART section can operate at much higher speeds, but the speed of the RS-232 transceiver is limited to 250Kbps beyond which the L200 cannot comply with the EIA/TIA-232 electrical characteristics. The device can operate either with a crystal on pins XTAL1 and XTAL2, or external clock source on XTAL1 pin.

Internal Enhanced Register Sets

The L200 UART has a set of enhanced registers providing control and monitoring functions. Interrupt enable/ disable and status, FIFO enable/disable, selectable TX and RX FIFO trigger levels, automatic hardware/ software flow control enable/disable, programmable baud rates, modem interface controls and status, and sleep mode are all standard features. Following a power on reset or an external reset (and operating in 16 or Intel Mode), the registers defaults to the reset condition and is compatible with the XR16L580.

RS-232 Interface

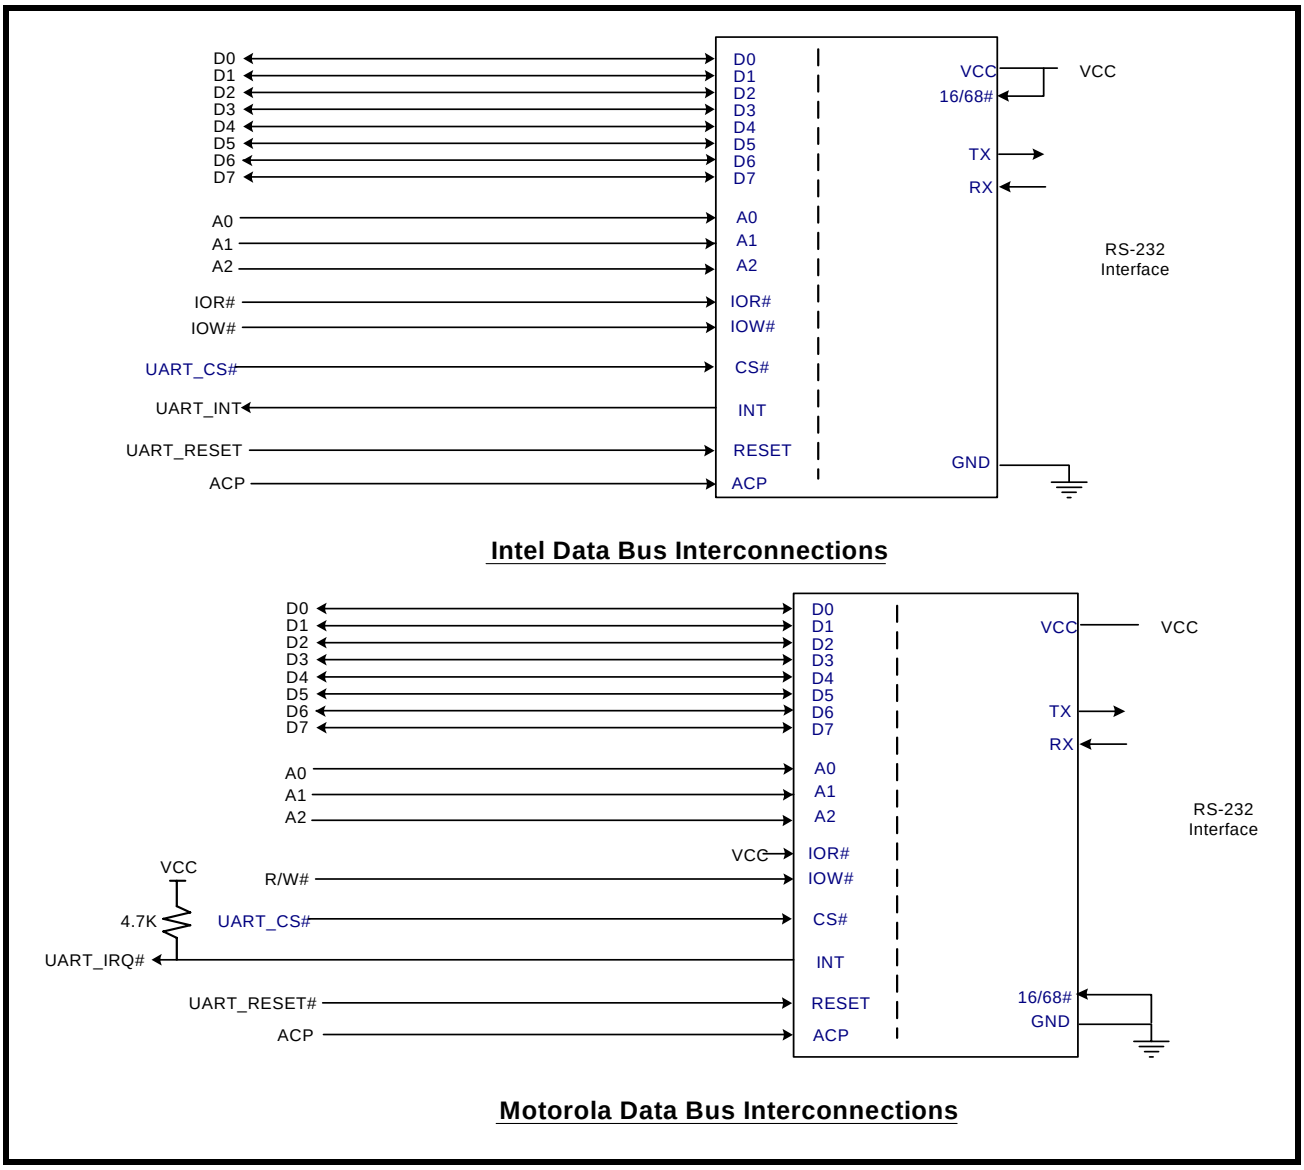
The L200 includes RS-232 drivers/receivers for the TXD and RXD signals (If more modem input and output signals are needed, see the XR19L220 and XR19L210). This feature eliminates the need for an external RS-232 transceiver. The charge pump provides output voltages of +5V and -5V for its drivers over the 3.0V to 5.5V VCC supply voltage. The serial output TX swings between -5V (inactive) and 5V (active) RS-232 voltage levels. The serial input RX is an RS-232 receiver and can take any voltage swing from -15V to +15V. The receiver is always active, even in Partial or Full Sleep modes. The RS-232 drivers guarantee a data rate of 250Kbps even when fully loaded with 3Kohm in parallel with 1000pF load. Also, the slew rate of the driver output is internally limited to a maximum of 30V/us in order to meet the EIA-232F standard.

2.0 FUNCTIONAL DESCRIPTIONS

2.1 CPU Interface

The CPU interface is 8 data bits wide with 3 address lines and control signals to execute data bus read and write transactions. The L200 data interface supports the Intel compatible types of CPUs and it is compatible to the industry standard 16C550 UART. No clock (oscillator nor external clock) is required to operate a data bus transaction. Each bus cycle is asynchronous using CS#, IOR# and IOW# or R/W# inputs. A typical data bus interconnection for Intel and Motorola mode is shown in **Figure 3**.

FIGURE 3. XR19L200 TYPICAL INTEL/MOTOROLA DATA BUS INTERCONNECTIONS



2.2 5-Volt Tolerant Inputs

The CMOS/TTL level inputs of the L200 can accept up to 5V inputs when operating at 3.3V. Note that the XTAL1 pin is not 5V tolerant when an external clock supply is used.

2.3 Device Hardware Reset

The RESET or RESET# input resets the internal registers and the serial interface outputs in both channels to their default state (see Table 11). An active pulse of longer than 40 ns duration will be required to activate the reset function in the device.

2.4 Device Identification and Revision

The XR19L200 provides a Device Identification code and a Device Revision code to distinguish the part from other devices and revisions. To read the identification code from the part, it is required to set the baud rate generator registers DLL and DLM both to 0x00. Now reading the content of the DLM will provide 0x01 to indicate functional compatibility with XR16L580 and reading the content of DLL will provide the revision of the part; for example, a reading of 0x01 means revision A.

2.5 Internal Registers

The L200 has a set of enhanced registers for control, monitoring and data loading and unloading. The configuration register set is compatible to those already available in the standard 16C550. These registers function as data holding registers (THR/RHR), interrupt status and control registers (ISR/IER), a FIFO control register (FCR), receive line status and control registers, (LSR/LCR), modem status and control registers (MSR/MCR), programmable data rate (clock) divisor registers (DLL/DLM), and an user accessible Scratchpad register (SPR).

Beyond the general 16C550 features and capabilities, the L200 offers enhanced feature registers just like the XR16L580, namely, EFR, Xon1, Xoff 1, Xon1 and Xoff2 that provide automatic Xon/Xoff software flow control. All the register functions are discussed in full detail later in **"Section 3.0, UART INTERNAL REGISTERS" on page 15**.

2.6 DMA Mode

The DMA Mode (a legacy term) refers to data block transfer operation. The DMA mode affects the state of the RXRDY# and TXRDY# output pins available in the original 16C550. These pins are not available in the XR19L200. The DMA Enable bit (FCR bit-3) does not have any function in this device and can be a '0' or a '1'.

2.7 INT (IRQ#) Output

The interrupt output changes according to the operating mode and enhanced features setup. Table 1 and Table 2 below summarize the operating behavior for the transmitter and receiver in the Intel and Motorola modes. Also see Figures 16 through 19.

TABLE 1: INT (IRQ#) PIN OPERATION FOR TRANSMITTER

	FCR BIT-0 = 0 (FIFO DISABLED)	FCR BIT-0 = 1 (FIFO ENABLED)
INT Pin (I/M# = 1)	0 = one byte in THR 1 = THR empty	0 = FIFO above trigger level 1 = FIFO below trigger level or FIFO empty
IRQ# Pin (I/M# = 0)	1 = one byte in THR 0 = THR empty	1 = FIFO above trigger level 0 = FIFO below trigger level or FIFO empty

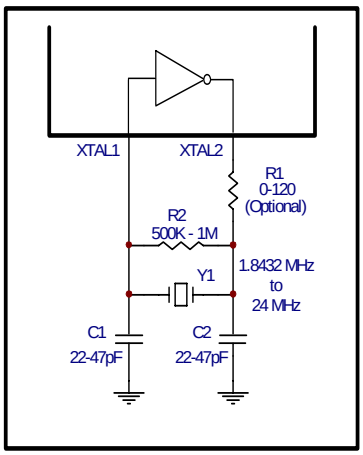
TABLE 2: INT (IRQ#) PIN OPERATION FOR RECEIVER

	FCR BIT-0 = 0 (FIFO DISABLED)	FCR BIT-0 = 1 (FIFO ENABLED)
INT Pin (I/M# = 1)	0 = no data 1 = 1 byte	0 = FIFO below trigger level 1 = FIFO above trigger level
IRQ# Pin (I/M# = 0)	1 = no data 0 = 1 byte	1 = FIFO below trigger level 0 = FIFO above trigger level

2.8 Crystal or External Clock Input

The L200 includes an on-chip oscillator (XTAL1 and XTAL2) to generate a clock when a crystal is connected between the XTAL1 and XTAL2 pins of the device. Alternatively, an external clock can be supplied through the XTAL1 pin. The CPU data bus does not require this clock for bus operation. The crystal oscillator provides a system clock to the Baud Rate Generators (BRG) section found in each of the UART. XTAL1 is the input to the oscillator or external clock input and XTAL2 pin is the bufferred output which can be used as a clock signal for other devices in the system. Please note that the input XTAL1 is not 5V tolerant and therefore, the maximum voltage at the pin should be VCC when an external clock is supplied. For programming details, see "Programmable Baud Rate Generator."

FIGURE 4. TYPICAL CRYSTAL CONNECTIONS

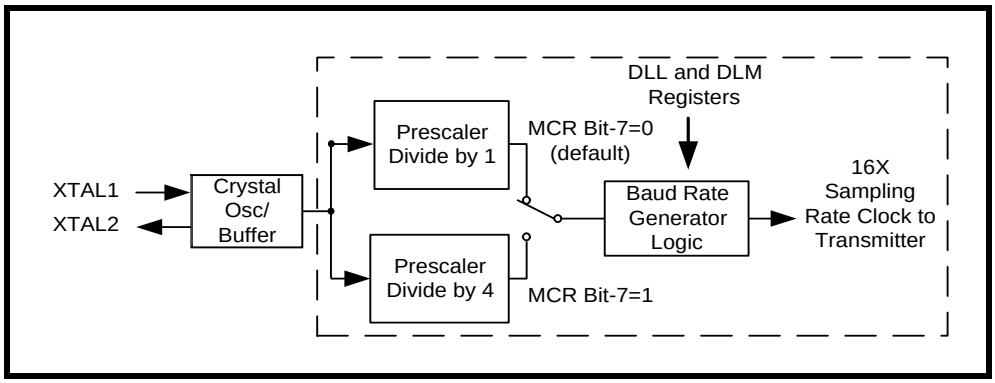


The on-chip oscillator is designed to use an industry standard microprocessor crystal (parallel resonant, fundamental frequency with 10-22 pF capacitance load, ESR of 20-120 ohms and 100ppm frequency tolerance) connected externally between the XTAL1 and XTAL2 pins. When VCC = 5V, the on-chip oscillator can operate with a crystal whose frequency is not greater than 24 MHz. On the other hand, the L200 can accept an external clock of up to 50MHz at XTAL1 pin also. Although the L200 can accept an exteran clock of up to 50MHz, the maximum data rate supported by the RS-232 drivers is 250Kbps. For further reading on the oscillator circuit please see the Application Note DAN108 on the EXAR web site at **http://www.exar.com.**

2.9 Programmable Baud Rate Generator

The L200 UART has its own Baud Rate Generator (BRG) with a prescaler. The prescaler is controlled by a software bit (bit-7) in the MCR register. This bit selects the prescaler to divide the input crystal or external clock by a factor of 1 or 4. The clock output of the prescaler goes to the BRG. The BRG further divides this clock by a programmable divisor (via DLL and DLM registers) between 1 and (2^{16} -1) to obtain a 16X sampling rate clock of the serial data rate. The sampling rate clock is used by the transmitter for data bit shifting and receiver for data sampling. The BRG divisor defaults to the maximum baud rate (DLL = 0x01 and DLM = 0x00) upon power up.

FIGURE 5. BAUD RATE GENERATOR AND PRESCALER



Programming the Baud Rate Generator Registers DLM and DLL provides the capability of selecting the operating data rate. Table 3 shows the standard data rates available with a 14.7456 MHz crystal or external clock at 16X sampling rate clock rate. When using a non-standard data rate crystal or external clock, the divisor value can be calculated for DLL/DLM with the following equation.

divisor (decimal) = (XTAL1 clock frequency / prescaler) / (serial data rate x 16)

TABLE 3: TYPICAL DATA RATES WITH A 14.7456 MHZ CRYSTAL OR EXTERNAL CLOCK

OUTPUT Data Rate MCR Bit-7=1	OUTPUT Data Rate MCR Bit-7=0 (DEFAULT)	DIVISOR FOR 16X Clock (Decimal)	DIVISOR FOR 16X Clock (HEX)	DLM PROGRAM VALUE (HEX)	DLL PROGRAM VALUE (HEX)	DATA RATE ERROR (%)
100	400	2304	900	09	00	0
600	2400	384	180	01	80	0
1200	4800	192	C0	00	C0	0
2400	9600	96	60	00	60	0
4800	19.2k	48	30	00	30	0
9600	38.4k	24	18	00	18	0
19.2k	76.8k	12	0C	00	0C	0
38.4k	153.6k	6	06	00	06	0
57.6k	230.4k	4	04	00	04	0

2.10 Transmitter

The transmitter section comprises of an 8-bit Transmit Shift Register (TSR) and 16 bytes of FIFO which includes a byte-wide Transmit Holding Register (THR). TSR shifts out every data bit with the 16X internal clock. A bit time is 16 clock periods. The transmitter sends the start-bit followed by the number of data bits, inserts the proper parity-bit if enabled, and adds the stop-bit(s). The status of the FIFO and TSR are reported in the Line Status Register (LSR bit-5 and bit-6).

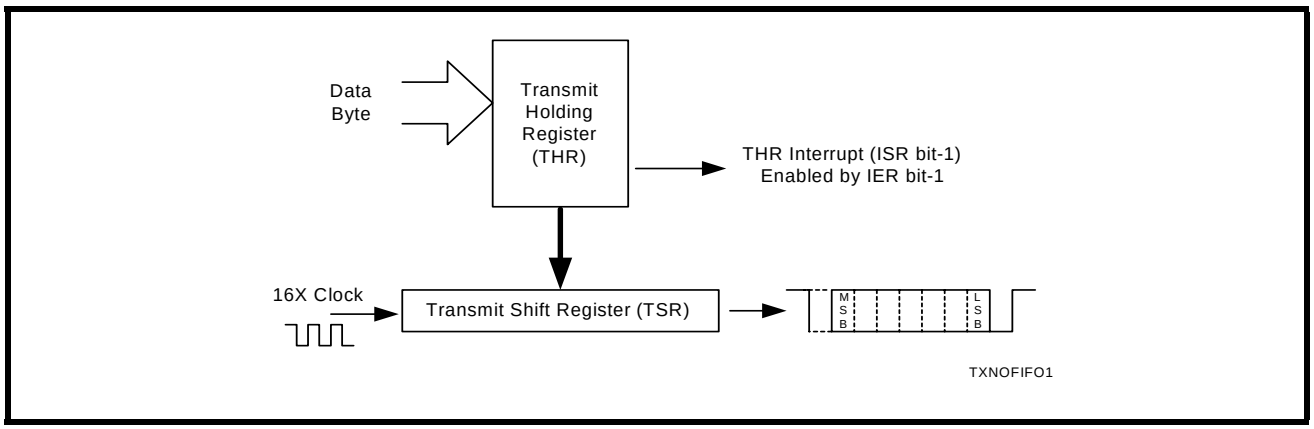
2.10.1 Transmit Holding Register (THR) - Write Only

The transmit holding register is an 8-bit register providing a data interface to the host processor. The host writes transmit data byte to the THR to be converted into a serial data stream including start-bit, data bits, parity-bit and stop-bit(s). The least-significant-bit (Bit-0) becomes first data bit to go out. The THR is the input register to the transmit FIFO of 16 bytes when FIFO operation is enabled by FCR bit-0. Every time a write operation is made to the THR, the FIFO data pointer is automatically bumped to the next sequential data location.

2.10.2 Transmitter Operation in non-FIFO Mode

The host loads transmit data to THR one character at a time. The THR empty flag (LSR bit-5) is set when the data byte is transferred to TSR. THR flag can generate a transmit empty interrupt (ISR bit-1) when it is enabled by IER bit-1. The TSR flag (LSR bit-6) is set when TSR becomes completely empty.

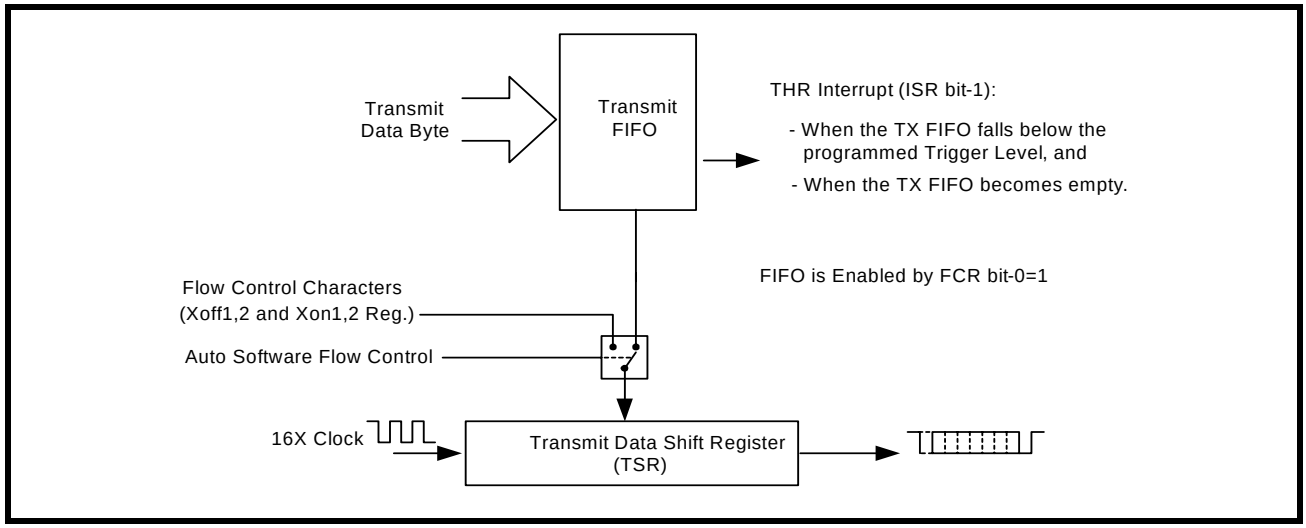
FIGURE 6. TRANSMITTER OPERATION IN NON-FIFO MODE



2.10.3 Transmitter Operation in FIFO Mode

The host may fill the transmit FIFO with up to 16 bytes of transmit data. The THR empty flag (LSR bit-5) is set whenever the FIFO is empty. The THR empty flag can generate a transmit empty interrupt (ISR bit-1) when the amount of data in the FIFO falls below its programmed trigger level. The transmit empty interrupt is enabled by IER bit-1. The Transmitter Empty Flag (LSR bit-6) is set when both the TSR and the FIFO become empty.

FIGURE 7. TRANSMITTER OPERATION IN FIFO AND FLOW CONTROL MODE



2.11 Receiver

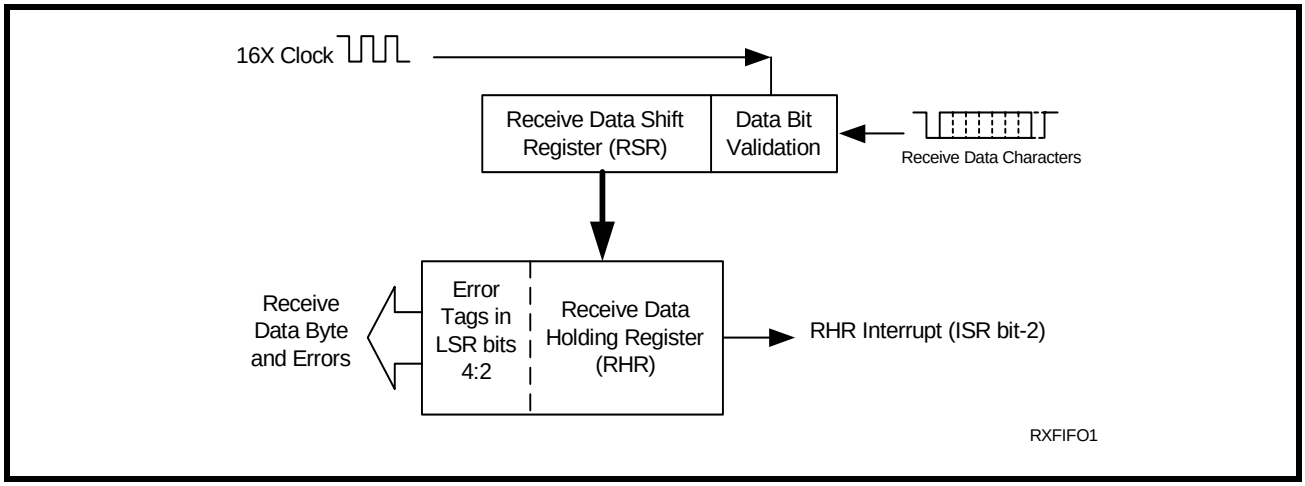
The receiver section contains an 8-bit Receive Shift Register (RSR) and 16 bytes of FIFO which includes a byte-wide Receive Holding Register (RHR). The RSR uses the 16X clock for timing. On the rising edge of RXD (or falling edge of RX) of a start or a false start bit, an internal receiver counter starts counting at the 16X clock rate. After 8 clocks the start bit period should be at the center of the start bit. At this time the start bit is sampled and if it is still LOW it is validated as a start bit. Evaluating the start bit in this manner prevents the receiver from assembling a false character. Each of the data, parity and stop bits is sampled at the middle of the bit to prevent false framing. If there were any error(s), they are reported in the LSR register bits 2-4. Upon unloading the receive data byte from RHR, the receive FIFO pointer is bumped and the error tags are immediately updated to reflect the status of the data byte in RHR register. RHR can generate a receive data ready interrupt

upon receiving a character or delay until it reaches the FIFO trigger level. Furthermore, data delivery to the host is guaranteed by a receive data ready time-out interrupt when data is not received for 4 word lengths as defined by LCR[1:0] plus 12 bits time. This is equivalent to 3.7-4.6 character times. The RHR interrupt is enabled by IER bit-0.

2.11.1 Receive Holding Register (RHR) - Read-Only

The Receive Holding Register is an 8-bit register that holds a receive data byte from the Receive Shift Register. It provides the receive data interface to the host processor. The RHR register is part of the receive FIFO of 16 bytes by 11-bits wide, the 3 extra bits are for the 3 error tags to be reported in LSR register. When the FIFO is enabled by FCR bit-0, the RHR contains the first data character received by the FIFO. After the RHR is read, the next character byte is loaded into the RHR and the errors associated with the current data byte are immediately updated in the LSR bits 2-4.

FIGURE 8. RECEIVER OPERATION IN NON-FIFO MODE



2.12 Auto Xon/Xoff (Software) Flow Control

When software flow control is enabled (**See Table 10**), the L200 compares one or two sequential receive data characters with the programmed Xon or Xoff-1,2 character value(s). If receive character(s) (RX) match the programmed values, the L200 will halt transmission (TX) as soon as the current character has completed transmission. When a match occurs, the Xoff (if enabled via IER bit-5) flag will be set and the interrupt output pin will be activated. Following a suspension due to a match of the Xoff character, the L200 will monitor the receive data stream for a match to the Xon-1,2 character. If a match is found, the L200 will resume operation and clear the flags (ISR bit-4).

Reset initially sets the contents of the Xon/Xoff 8-bit flow control registers to a logic 0. Following reset the user can write any Xon/Xoff value desired for software flow control. Different conditions can be set to detect Xon/Xoff characters (**See Table 10**) and suspend/resume transmissions. When double 8-bit Xon/Xoff characters are selected, the L200 compares two consecutive receive characters with two software flow control 8-bit values (Xon1, Xon2, Xoff1, Xoff2) and controls TX transmissions accordingly. Under the above described flow control mechanisms, flow control characters are not placed (stacked) in the user accessible RX data buffer or FIFO.

In the event that the receive buffer is overfilling and flow control needs to be executed, the L200 automatically sends an Xoff message (when enabled) via the serial TX output to the remote modem. The L200 sends the Xoff character(s) two-character-times (= time taken to send two characters at the programmed baud rate) after the receive FIFO crosses the programmed trigger level. To clear this condition, the L200 will transmit the programmed Xon character(s) as soon as receive FIFO is less than one trigger level below the programmed trigger level (see **Table 8**). **The table below describes this**.

TABLE 4: AUTO XON/XOFF (SOFTWARE) FLOW CONTROL

RX TRIGGER LEVEL	INT PIN ACTIVATION	XOFF CHARACTER(S) SENT (CHARACTERS IN RX FIFO)	XON CHARACTER(S) SENT (CHARACTERS IN RX FIFO)
1	1	1*	0
4	4	4*	1
8	8	8*	4
14	14	14*	8

** After the trigger level is reached, an xoff character is sent after a short span of time (= time required to send 2 characters); for example, after 2.083ms has elapsed for 9600 baud and 8-bit word length, no parity and 1 stop bit setting.*

2.13 Special Character Detect

A special character detect feature is provided to detect an 8-bit character when bit-5 is set in the Enhanced Feature Register (EFR). When this character (Xoff2) is detected, it will be placed in the FIFO along with normal incoming RX data.

The L200 compares each incoming receive character with the programmed Xoff-2 data. If a match exists, the received data will be transferred to the RX FIFO and ISR bit-4 will be set to indicate detection of special character. Although the Internal Register Table shows Xon, Xoff Registers with eight bits of character information, the actual number of bits is dependent on the programmed word length. Line Control Register (LCR) bits 0-1 defines the number of character bits, i.e., either 5 bits, 6 bits, 7 bits, or 8 bits. The word length selected by LCR bits 0-1 also determines the number of bits that will be used for the special character comparison. Bit-0 in the Xon, Xoff Registers corresponds with the LSB bit for the receive character.

2.14 Sleep Modes with Wake-Up Interrupt

There are two levels of power management integrated in the L200. The device is low power with low operational and standby supply currents. In the Partial Sleep mode, the internal oscillator of the UART or charge pump of the RS-232 transceiver is turned off to reduce the power consumption. In the Full Sleep mode, both the oscillator and the charge pump are turned off.

2.14.1 Partial Sleep Mode

There are two different partial sleep modes. In the first mode, the UART is in sleep mode and the RS-232 transceiver is active. In the other mode, the UART is active but the charge pump of the RS-232 transceiver is turned off.

2.14.1.1 UART in sleep mode, RS-232 transceiver active

If the ACP pin is LOW, then the charge pump for the RS-232 transceiver will always be active. But the UART portion in the L200 can still enter sleep mode if all of these conditions are satisfied:

- no interrupts pending (ISR bit-0 = 1)
- the 16-bit divisor programmed in DLM and DLL registers is a non-zero value
- sleep mode is enabled (IER bit-4 = 1)
- RXD input pin is idling LOW

The L200 stops its crystal oscillator to conserve power in this mode. The user can check the XTAL2 pin for no clock output as an indication that the device has entered the partial sleep mode.

The UART portion in the L200 resumes normal operation or active mode by any of the following:

- a receive data start bit transition on the RXD input (LOW to HIGH)
- a data byte is loaded to the transmitter, THR or FIFO

The UART portion in the L200 will return to the sleep mode automatically after all interrupting conditions have been serviced and cleared. In any case, the sleep mode will not be entered while an interrupt is pending. The UART portion of the L200 will stay in the sleep mode of operation until it is disabled by setting IER bit-4 to a logic 0.

2.14.1.2 UART active, charge pump of RS-232 transceiver shut down

If the ACP pin is HIGH and the UART portion of the L200 is not in sleep mode, then the charge pump will automatically shut down to conserve power if the following conditions are true:

- no activity on the TXD output signals
- RXD input signal has been idling LOW for approximately 30 seconds

When these conditions are satisfied, the L200 shuts down the charge pump and tri-states the RS-232 drivers to conserve power. In this mode, the RS-232 receivers are fully active and the internal registers of the L200 can be accessed. The time for the charge pump to resume normal operation after exiting the sleep mode is typically 45µs. It will wake up by any of the following:

- a receive data start bit transition on the RXD input (LOW to HIGH)
- a data byte is loaded to the transmitter, THR or FIFO

Because the receivers are fully active when the charge pump is turned off, any data received will be transferred to/from the UART without any issues.

2.14.2 Full Sleep Mode

In full sleep mode, the L210 shuts down the charge pump and the internal oscillator. The L210 enters the full sleep mode if the following conditions are satisfied:

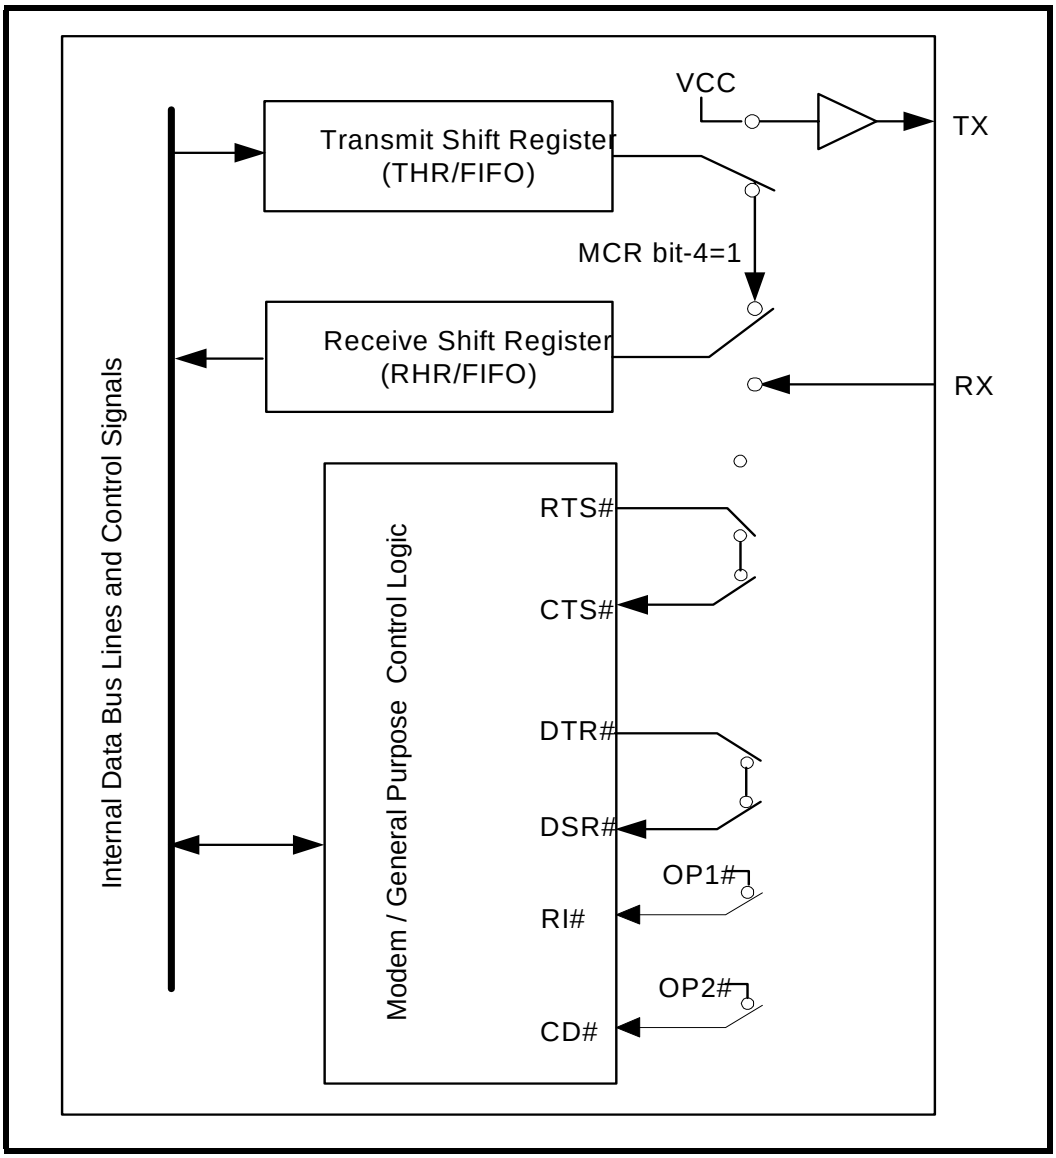
- the UART portion of the L210 is already in sleep mode (no output on XTAL2)
- the ACP (Autosleep for Charge Pump) pin is HIGH

When these conditions are satisfied, both the UART and the charge pump will be in the sleep mode. In this mode, the RS-232 receivers are fully active and the internal registers of the L200 can be accessed. The L200 exits the full sleep mode if either the ACP pin becomes LOW or the internal oscillator starts up. The time for the charge pump to resume normal operation after exiting the full sleep mode is typically 45µs.

2.15 Internal Loopback

The L200 UART provides an internal loopback capability for system diagnostic purposes. The internal loopback mode is enabled by setting MCR register bit-4 to logic 1. All regular UART functions operate normally including automatic hardware and software flow control. **Figure 9** below shows how the internal UART signals are re-configured. Transmit data from the transmit shift register output is internally routed to the receive shift register input allowing the system to receive the same data that it was sending. The TX and RTS# pins are held HIGH while RX and CTS# inputs are ignored. Caution: the RX input pin must be held at inactive during loopback test else upon exiting the loopback test the UART may detect and report a false "break" signal.

FIGURE 9. INTERNAL LOOP BACK



3.0 UART INTERNAL REGISTERS

The L200 has a set of configuration registers selected by address lines A0, A1 and A2 with CS# asserted. The complete register set is shown on Table 5 and Table 6.

TABLE 5: UART INTERNAL REGISTERS

ADDRESSES A2 A1 A0	REGISTER	READ/WRITE	COMMENTS
16C550 COMPATIBLE REGISTERS			
0 0 0	RHR - Receive Holding Register THR - Transmit Holding Register	Read-only Write-only	LCR[7] = 0
0 0 0	DLL - Divisor Latch Low Byte	Read/Write	LCR[7] = 1
0 0 1	DLM - Divisor Latch High Byte	Read/Write	
0 0 0	DREV - Device Revision Code	Read-only	DLL = 0x00, DLM = 0x00 and LCR[7] = 1
0 0 1	DVID - Device Identification Code	Read-only	
0 0 1	IER - Interrupt Enable Register	Read/Write	LCR[7] = 0

4.0 INTERNAL REGISTERS DESCRIPTIONS

4.1 Receive Holding Register (RHR) - Read- Only

SEE "RECEIVER" ON PAGE 10.

4.2 Transmit Holding Register (THR) - Write-Only

SEE "TRANSMITTER" ON PAGE 9.

4.3 Baud Rate Generator Divisors (DLL and DLM) - Read/Write

The Baud Rate Generator (BRG) is a 16-bit counter that generates the data rate for the transmitter. The rate is programmed through registers DLL and DLM which are only accessible when LCR bit-7 is set to '1'. **SEE "PROGRAMMABLE BAUD RATE GENERATOR" ON PAGE 8.** for more details.

4.4 Interrupt Enable Register (IER) - Read/Write

The Interrupt Enable Register (IER) masks the interrupts from receive data ready, transmit empty, line status and modem status registers. These interrupts are reported in the Interrupt Status Register (ISR).

4.4.1 IER versus Receive FIFO Interrupt Mode Operation

When the receive FIFO (FCR BIT-0 = 1) and receive interrupts (IER BIT-0 = 1) are enabled, the RHR interrupts (see ISR bits 2 and 3) status will reflect the following:

A. The receive data available interrupts are issued to the host when the FIFO has reached the programmed trigger level. It will be cleared when the FIFO drops below the programmed trigger level.

B. FIFO level will be reflected in the ISR register when the FIFO trigger level is reached. Both the ISR register status bit and the interrupt will be cleared when the FIFO drops below the trigger level.

C. The receive data ready bit (LSR BIT-0) is set as soon as a character is transferred from the shift register to the receive FIFO. It is reset when the FIFO is empty.

4.4.2 IER versus Receive/Transmit FIFO Polled Mode Operation

When FCR bit-0 equals a logic 1 for FIFO enable; resetting IER bits 0-3 enables the XR19L200 in the FIFO polled mode of operation. Since the receiver and transmitter have separate bits in the LSR either or both can be used in the polled mode by selecting respective transmit or receive control bit(s).

A. LSR BIT-0 indicates there is data in RHR or RX FIFO.

B. LSR BIT-1 indicates an overrun error has occurred and that data in the FIFO may not be valid.

C. LSR BIT 2-4 provides the type of receive data errors encountered for the data byte in RHR, if any.

D. LSR BIT-5 indicates THR is empty.

E. LSR BIT-6 indicates when both the transmit FIFO and TSR are empty.

F. LSR BIT-7 indicates a data error in at least one character in the RX FIFO.

IER[0]: RHR Interrupt Enable

The receive data ready interrupt will be issued when RHR has a data character in the non-FIFO mode or when the receive FIFO has reached the programmed trigger level in the FIFO mode.

- Logic 0 = Disable the receive data ready interrupt (default).
- Logic 1 = Enable the receiver data ready interrupt.

IER[1]: THR Interrupt Enable

This bit enables the Transmit Ready interrupt which is issued whenever the THR becomes empty in the non-FIFO mode or when data in the FIFO falls below the programmed trigger level in the FIFO mode. If the THR is empty when this bit is enabled, an interrupt will be generated.

- Logic 0 = Disable Transmit Ready interrupt (default).
- Logic 1 = Enable Transmit Ready interrupt.

IER[2]: Receive Line Status Interrupt Enable

If any of the LSR register bits 1, 2, 3 or 4 is a logic 1, it will generate an interrupt to inform the host controller about the error status of the current data byte in FIFO. LSR bit-1 generates an interrupt immediately when the character has been received. LSR bits 2-4 generate an interrupt when the character with errors is read out of the FIFO.

- Logic 0 = Disable the receiver line status interrupt (default).
- Logic 1 = Enable the receiver line status interrupt.

IER[3]: Modem Status Interrupt Enable

- Logic 0 = Disable the modem status register interrupt (default).
- Logic 1 = Enable the modem status register interrupt.

IER[4]: Sleep Mode Enable (requires EFR bit-4 = 1)

- Logic 0 = Disable Sleep Mode (default).
- Logic 1 = Enable Sleep Mode. See Sleep Mode section for further details.

IER[5]: Xoff Interrupt Enable (requires EFR bit-4=1)

- Logic 0 = Disable the software flow control, receive Xoff interrupt (default).
- Logic 1 = Enable the software flow control, receive Xoff interrupt. See Software Flow Control section for details.

IER[7:6]: Reserved

For proper functionality, these bits should remain at a ’0’.

4.5 Interrupt Status Register (ISR) - Read-Only

The UART provides multiple levels of prioritized interrupts to minimize external software interaction. The Interrupt Status Register (ISR) provides the user with six interrupt status bits. Performing a read cycle on the ISR will give the user the current highest pending interrupt level to be serviced, others are queued up to be serviced next. No other interrupts are acknowledged until the pending interrupt is serviced. The Interrupt Source Table, Table 7, shows the data values (bit 0-5) for the interrupt priority levels and the interrupt sources associated with each of these interrupt levels.

4.5.1 Interrupt Generation:

- LSR is by any of the LSR bits 1, 2, 3 and 4.
- RXRDY is by RX trigger level.
- RXRDY Time-out is by a 4-char plus 12 bits delay timer.
- TXRDY is by TX trigger level or TX FIFO empty.
- MSR is by any of the MSR bits 0, 1, 2 and 3.
- Receive Xoff/Special character is by detection of a Xoff or Special character.
- Wake-up Interrupt is when the device wakes up from sleep mode. See Sleep Mode section for more details.

4.5.2 Interrupt Clearing:

- LSR interrupt is cleared by reading the LSR register (but FIFO error bit does not clear until the character(s) that generated the interrupt(s) is (are) read from the FIFO).
- RXRDY interrupt is cleared by reading data until FIFO falls below the trigger level.
- RXRDY Time-out interrupt is cleared by reading the RHR register.
- TXRDY interrupt is cleared by reading the ISR register or writing to the THR register.
- MSR interrupt is cleared by reading the MSR register.
- Xoff interrupt is cleared by reading the ISR or when Xon character(s) is received.
- Special character interrupt is cleared by reading the ISR or after the next character is received.
- Wake-up interrupt is cleared by reading the ISR register.

TABLE 7: INTERRUPT SOURCE AND PRIORITY LEVEL

PRIORITY LEVEL	ISR REGISTER STATUS BITS						SOURCE OF INTERRUPT
	BIT-5	BIT-4	BIT-3	BIT-2	BIT-1	BIT-0	
1	0	0	0	1	1	0	LSR (Receiver Line Status Register)
2	0	0	1	1	0	0	RXRDY (Receive Data Time-out)
3	0	0	0	1	0	0	RXRDY (Received Data Ready)
4	0	0	0	0	1	0	TXRDY (Transmit Ready)
5	0	0	0	0	0	0	MSR (Modem Status Register)
6	0	1	0	0	0	0	RXRDY (Received Xoff or Special character)
-	0	0	0	0	0	1	None (default) or Wake-up Interrupt

ISR[0]: Interrupt Status

- Logic 0 = An interrupt is pending and the ISR contents may be used as a pointer to the appropriate interrupt service routine.
- Logic 1 = No interrupt pending (default condition) or wake-up interrupt. The wake-up interrupt is issued when the L200 has been awakened from sleep mode.

ISR[3:1]: Interrupt Status

These bits indicate the source for a pending interrupt at interrupt priority levels (See Interrupt Source **Table 7**).

ISR[4]: Xoff/Xon or Special Character Interrupt Status

This bit is enabled when EFR bit-4 is set to a logic 1. ISR bit-4 indicates that the receiver detected a data match of the Xoff character(s). If this is an Xoff/Xon interrupt, it can be cleared by a read to the ISR. If it is a special character interrupt, it can be cleared by reading ISR or it will automatically clear after the next character is received.

ISR[5]: RTS#/CTS# Interrupt Status

This bit is enabled when EFR bit-4 is set to a logic 1. ISR bit-5 indicates that the CTS# or RTS# has been de-asserted.

ISR[7:6]: FIFO Enable Status

These bits are set to a logic 0 when the FIFOs are disabled. They are set to a logic 1 when the FIFOs are enabled.

4.6 FIFO Control Register (FCR) - Write-Only

This register is used to enable the FIFOs, clear the FIFOs, set the transmit/receive FIFO trigger levels, and select the DMA mode. The DMA, and FIFO modes are defined as follows:

FCR[0]: TX and RX FIFO Enable

- Logic 0 = Disable the transmit and receive FIFO (default).
- Logic 1 = Enable the transmit and receive FIFOs. This bit must be set to logic 1 when other FCR bits are written or they will not be programmed.

FCR[1]: RX FIFO Reset

This bit is only active when FCR bit-0 is a ‘1’.

- Logic 0 = No receive FIFO reset (default)
- Logic 1 = Reset the receive FIFO pointers and FIFO level counter logic (the receive shift register is not cleared or altered). This bit will return to a logic 0 after resetting the FIFO.

FCR[2]: TX FIFO Reset

This bit is only active when FCR bit-0 is a ‘1’.

- Logic 0 = No transmit FIFO reset (default).
- Logic 1 = Reset the transmit FIFO pointers and FIFO level counter logic (the transmit shift register is not cleared or altered). This bit will return to a logic 0 after resetting the FIFO.

FCR[3]: DMA Mode Select (Legacy)

This bit has no function and should be left at ’0’.

FCR[5:4]: Transmit FIFO Trigger Select

(’00’ = default, TX trigger level = 1)

These 2 bits set the trigger level for the transmit FIFO. The UART will issue a transmit interrupt when the number of characters in the FIFO falls below the selected trigger level, or when it gets empty in case that the FIFO did not get filled over the trigger level on last re-load. **Table 8** below shows the selections. EFR bit-4 must be set to ‘1’ before these bits can be accessed.

FCR[7:6]: Receive FIFO Trigger Select

('00' = default, RX trigger level =1)

These 2 bits are used to set the trigger level for the receive FIFO. The UART will issue a receive interrupt when the number of the characters in the FIFO crosses the trigger level. Table 8 shows the selections.

TABLE 8: TRANSMIT AND RECEIVE FIFO TRIGGER LEVEL SELECTION

FCR BIT-7	FCR BIT-6	FCR BIT-5	FCR BIT-4	RECEIVE TRIGGER LEVEL	TRANSMIT TRIGGER LEVEL	COMPATIBILITY
		0	0		1 (default)	16L580 and 16C580 compatible.
		0	1		4	
		1	0		8	
		1	1		14	
0	0			1 (default)		16L580, 16C550, 16C580, 16C554, 16C2550 and 16C2552 compatible
0	1			4		
1	0			8		
1	1			14		

4.7 Line Control Register (LCR) - Read/Write

The Line Control Register is used to specify the asynchronous data communication format. The word or character length, the number of stop bits, and the parity are selected by writing the appropriate bits in this register.

LCR[1:0]: TX and RX Word Length Select

These two bits specify the word length to be transmitted or received.

BIT-1	BIT-0	WORD LENGTH
0	0	5 (default)
0	1	6
1	0	7
1	1	8

LCR[2]: TX and RX Stop-bit Length Select

The length of stop bit is specified by this bit in conjunction with the programmed word length.

BIT-2	WORD LENGTH	STOP BIT LENGTH (BIT TIME(S))
0	5,6,7,8	1 (default)
1	5	1-1/2
1	6,7,8	2

LCR[3]: TX and RX Parity Select

Parity or no parity can be selected via this bit. The parity bit is a simple way used in communications for data integrity check. See Table 9 for parity selection summary below.

- Logic 0 = No parity.
- Logic 1 = A parity bit is generated during the transmission while the receiver checks for parity error of the data character received.

LCR[4]: TX and RX Parity Select

If the parity bit is enabled with LCR bit-3 set to a logic 1, LCR BIT-4 selects the even or odd parity format.

- Logic 0 = ODD Parity is generated by forcing an odd number of logic 1's in the transmitted character. The receiver must be programmed to check the same format (default).
- Logic 1 = EVEN Parity is generated by forcing an even number of logic 1's in the transmitted character. The receiver must be programmed to check the same format.

LCR[5]: TX and RX Parity Select

If the parity bit is enabled, LCR BIT-5 selects the forced parity format.

- LCR BIT-5 = logic 0, parity is not forced (default).
- LCR BIT-5 = logic 1 and LCR BIT-4 = logic 0, parity bit is forced to a logical 1 for the transmit and receive data.
- LCR BIT-5 = logic 1 and LCR BIT-4 = logic 1, parity bit is forced to a logical 0 for the transmit and receive data.

TABLE 9: PARITY SELECTION

LCR BIT-5	LCR BIT-4	LCR BIT-3	PARITY SELECTION
X	X	0	No parity
0	0	1	Odd parity
0	1	1	Even parity
1	0	1	Force parity to mark, "1"
1	1	1	Forced parity to space, "0"

LCR[6]: Transmit Break Enable

When enabled, the Break control bit causes a break condition to be transmitted (the TX output is forced LOW). This condition remains, until disabled by setting LCR bit-6 to a logic 0.

- Logic 0 = No TX break condition (default).
- Logic 1 = Forces the transmitter output (TX) LOW for alerting the remote receiver of a line break condition.

LCR[7]: Baud Rate Divisors Enable

Baud rate generator divisor (DLL/DLM) enable.

- Logic 0 = Data registers are selected (default).
- Logic 1 = Divisor latch registers are selected.

4.8 Modem Control Register (MCR) or General Purpose Outputs Control - Read/Write

The MCR register is used for controlling the serial/modem interface signals or general purpose inputs/outputs.

MCR[0]: DTR# Output

The DTR# output is not available as an output on this device. But for 16C550 compatibility, it can still be used in internal loopback mode.

- Logic 0 = Force DTR output HIGH (default).
- Logic 1 = Force DTR output LOW.

MCR[1]: RTS# Output

The RTS# output is not available as an output on this device. But for 16C550 compatibility, it can still be used in internal loopback mode.

- Logic 0 = Force RTS output HIGH (default).
- Logic 1 = Force RTS output LOW.

MCR[2]: OP1# (legacy term)

The OP1# output is not available on the XR19L200, however, it is available in internal loopback. In the Internal Loopback Mode, this bit controls the state of the modem input RI bit in the MSR register as shown in **Figure 9**.

- Logic 0 = OP1# is HIGH (default).
- Logic 1 = OP1# is LOW.

In the Internal Loopback Mode, this bit controls the state of the modem input RI bit in the MSR register as shown in **Figure 9**.

MCR[3]: INT Output Enable or OP2# (legacy term)

This bit enables and disables the operation of interrupt output, INT in the Intel mode. If INT output is not used, OP2# can be used as a general purpose output in the Intel mode. In the Motorola mode, this bit must be set to logic 0.

- Logic 0 = INT output disabled (three state mode) in Intel mode (default).
- Logic 1 = INT output enabled (active mode) in Intel mode.

In the Internal Loopback Mode, this bit functions like the OP2# in the 16C550 and is used to set the state of the modem input CD bit in the MSR register.

MCR[4]: Internal Loopback Enable

- Logic 0 = Disable loopback mode (default).
- Logic 1 = Enable local loopback mode, see loopback section and **Figure 9**.

MCR[5]: Xon-Any Enable

- Logic 0 = Disable Xon-Any function (for 16C550 compatibility, default).
- Logic 1 = Enable Xon-Any function. In this mode, any RX character received will resume transmit operation. The RX character will be loaded into the RX FIFO, unless the RX character is an Xon or Xoff character and the L200 is programmed to use the Xon/Xoff flow control.

MCR[6]: Reserved

For proper functionality, this bit should be set to a logic 0.

MCR[7]: BRG Clock Prescaler Select

- Logic 0 = Divide by one. The input clock from the crystal or external clock is fed directly to the Programmable Baud Rate Generator without further modification, i.e., divide by one (default).
- Logic 1 = Divide by four. The prescaler divides the input clock from the crystal or external clock by four and feeds it to the Programmable Baud Rate Generator, hence, data rates get reduced 4 times.

4.9 Line Status Register (LSR) - Read Only

This register provides the status of data transfers between the UART and the host.

LSR[0]: Receive Data Ready Indicator

- Logic 0 = No data in receive holding register or FIFO (default).
- Logic 1 = Data has been received and is saved in the receive holding register or FIFO.

LSR[1]: Receiver Overrun Flag

- Logic 0 = No overrun error (default).
- Logic 1 = Overrun error. A data overrun error condition occurred in the receive shift register. This happens when additional data arrives while the FIFO is full. In this case the previous data in the receive shift register is overwritten. Note that under this condition the data byte in the receive shift register is not transferred into the FIFO, therefore the data in the FIFO is not corrupted by the error.

LSR[2]: Receive Data Parity Error Flag

- Logic 0 = No parity error (default).
- Logic 1 = Parity error. The receive character in RHR does not have correct parity information and is suspect. This error is associated with the character available for reading in RHR.

LSR[3]: Receive Data Framing Error Flag

- Logic 0 = No framing error (default).
- Logic 1 = Framing error. The receive character did not have a valid stop bit(s). This error is associated with the character available for reading in RHR.

LSR[4]: Receive Break Flag

- Logic 0 = No break condition (default).
- Logic 1 = The receiver received a break signal (RX was LOW for at least one character frame time). In the FIFO mode, only one break character is loaded into the FIFO. The break indication remains until the RX input returns to the idle condition.

LSR[5]: Transmit Holding Register Empty Flag

This bit is the Transmit Holding Register Empty indicator. The THR bit is set to a logic 1 when the last data byte is transferred from the transmit holding register to the transmit shift register. The bit is reset to logic 0 concurrently with the data loading to the transmit holding register by the host. In the FIFO mode this bit is set when the transmit FIFO is empty, it is cleared when the transmit FIFO contains at least 1 byte.

LSR[6]: THR and TSR Empty Flag

This bit is set to a logic 1 whenever the transmitter goes idle. It is set to logic 0 whenever either the THR or TSR contains a data character. In the FIFO mode this bit is set to a logic 1 whenever the transmit FIFO and transmit shift register are both empty.

LSR[7]: Receive FIFO Data Error Flag

- Logic 0 = No FIFO error (default).
- Logic 1 = A global indicator for the sum of all error bits in the RX FIFO. At least one parity error, framing error or break indication is in the FIFO data. This bit clears when there is no more error(s) in any of the bytes in the RX FIFO.

4.10 Modem Status Register (MSR) - Read Only

This register provides the current state of the modem interface input signals. In the normal mode of operation, none of the modem inputs (CTS, DSR, RI and CD) will change. However, all of the modem inputs can be controlled in internal loopback mode. Lower four bits of this register are used to indicate the changed information. These bits are set to a logic 1 whenever a signal from the modem changes state.

MSR[0]: Delta CTS Input Flag

- Logic 0 = No change on CTS input (default).
- Logic 1 = The CTS input has changed state since the last time it was monitored. A modem status interrupt will be generated if MSR interrupt is enabled (IER bit-3).

MSR[1]: Delta DSR Input Flag

- Logic 0 = No change on DSR input (default).
- Logic 1 = The DSR input has changed state since the last time it was monitored. A modem status interrupt will be generated if MSR interrupt is enabled (IER bit-3).

MSR[2]: Delta RI Input Flag

- Logic 0 = No change on RI input (default).
- Logic 1 = The RI input has changed from LOW to HIGH, ending of the ringing signal. A modem status interrupt will be generated if MSR interrupt is enabled (IER bit-3).

MSR[3]: Delta CD Input Flag

- Logic 0 = No change on CD input (default).
- Logic 1 = Indicates that the CD input has changed state since the last time it was monitored. A modem status interrupt will be generated if MSR interrupt is enabled (IER bit-3).

MSR[4]: CTS Input Status

CTS pin may function as automatic hardware flow control signal input if it is enabled and selected by Auto CTS (EFR bit-7). Auto CTS flow control allows starting and stopping of local data transmissions based on the modem CTS signal. A HIGH on the CTS pin will stop UART transmitter as soon as the current character has finished transmission, and a LOW will resume data transmission. Normally MSR bit-4 bit is the complement of the CTS input. However in the loopback mode, this bit is equivalent to the RTS bit in the MCR register. The CTS input may be used as a general purpose input when the modem interface is not used.

MSR[5]: DSR Input Status

Normally this bit is the complement of the DSR input. In the loopback mode, this bit is equivalent to the DTR bit in the MCR register. The DSR input may be used as a general purpose input when the modem interface is not used.

MSR[6]: RI Input Status

Normally this bit is the complement of the RI input. In the loopback mode this bit is equivalent to bit-2 in the MCR register. The RI input may be used as a general purpose input when the modem interface is not used.

MSR[7]: CD Input Status

Normally this bit is the complement of the CD input. In the loopback mode this bit is equivalent to bit-3 in the MCR register. The CD input may be used as a general purpose input when the modem interface is not used.

4.11 Scratchpad Register (SPR) - Read/Write

This is a 8-bit general purpose register for the user to store temporary data. The content of this register is preserved during sleep mode but becomes 0xFF (default) after a reset or a power off-on cycle.

4.12 Baud Rate Generator Registers (DLL and DLM) - Read/Write

The concatenation of the contents of DLM and DLL gives the 16-bit divisor value which is used to calculate the baud rate:

- Baud Rate = (Clock Frequency / 16) / Divisor

See MCR bit-7 and the baud rate table also.

4.13 Device Identification Register (DVID) - Read Only

This register contains the device ID (0x01 for XR19L200). Prior to reading this register, DLL and DLM should be set to 0x00.

4.14 Device Revision Register (DREV) - Read Only

This register contains the device revision information. For example, 0x01 means revision A. Prior to reading this register, DLL and DLM should be set to 0x00.

4.15 Enhanced Feature Register (EFR)

Enhanced features are enabled or disabled using this register. Bit 0-3 provide single or dual consecutive character software flow control selection (see Table 10). When the Xon1 and Xon2 and Xoff1 and Xoff2 modes are selected, the double 8-bit words are concatenated into two sequential characters. Caution: note that whenever changing the TX or RX flow control bits, always reset all bits back to logic 0 (disable) before programming a new setting.

EFR[3:0]: Software Flow Control Select

Single character and dual sequential characters software flow control is supported. Combinations of software flow control can be selected by programming these bits.

TABLE 10: SOFTWARE FLOW CONTROL FUNCTIONS

EFR BIT-3 CONT-3	EFR BIT-2 CONT-2	EFR BIT-1 CONT-1	EFR BIT-0 CONT-0	TRANSMIT AND RECEIVE SOFTWARE FLOW CONTROL
0	0	0	0	No TX and RX flow control (default and reset)
0	0	X	X	No transmit flow control
1	0	X	X	Transmit Xon1, Xoff1
0	1	X	X	Transmit Xon2, Xoff2
1	1	X	X	Transmit Xon1 and Xon2, Xoff1 and Xoff2
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares Xon1, Xoff1
X	X	0	1	Receiver compares Xon2, Xoff2
1	0	1	1	Transmit Xon1, Xoff1 Receiver compares Xon1 or Xon2, Xoff1 or Xoff2
0	1	1	1	Transmit Xon2, Xoff2 Receiver compares Xon1 or Xon2, Xoff1 or Xoff2
1	1	1	1	Transmit Xon1 and Xon2, Xoff1 and Xoff2, Receiver compares Xon1 and Xon2, Xoff1 and Xoff2
0	0	1	1	No transmit flow control, Receiver compares Xon1 and Xon2, Xoff1 and Xoff2

EFR[4]: Enhanced Function Bits Enable

Enhanced function control bit. This bit enables IER bits 4-7, ISR bits 4-5, FCR bits 4-5, MCR bits 2, 5, 6 and 7 to be modified. After modifying any enhanced bits, EFR bit-4 can be set to a logic 0 to latch the new values. This feature prevents legacy software from altering or overwriting the enhanced functions once set. Normally, it is recommended to leave it enabled, logic 1.

- Logic 0 = modification disable/latch enhanced features. IER bits 4-7, ISR bits 4-5, FCR bits 4-5, and MCR bits 2, 5-7 are saved to retain the user settings. After a reset, the IER bits 4-7, ISR bits 4-5, FCR bits 4-5, and MCR bits 2, 5-7 are set to a logic 0 to be compatible with ST16C550 mode (default).
- Logic 1 = Enables the above-mentioned register bits to be modified by the user.

EFR[5]: Special Character Detect Enable

- Logic 0 = Special Character Detect Disabled (default).
- Logic 1 = Special Character Detect Enabled. The UART compares each incoming receive character with data in Xoff-2 register. If a match exists, the receive data will be transferred to FIFO and ISR bit-4 will be set to indicate detection of the special character. Bit-0 corresponds with the LSB bit of the receive character. If flow control is set for comparing Xon1, Xoff1 (EFR [1:0]= '10') then flow control and special character work normally. However, if flow control is set for comparing Xon2, Xoff2 (EFR[1:0]= '01') then flow control works normally, but Xoff2 will not go to the FIFO, and will generate an Xoff interrupt and a special character interrupt, if enabled via IER bit-5.

EFR[7:6]: Reserved

For proper functionality, these bits should remain at a '0'.

4.16 Software Flow Control Registers (XOFF1, XOFF2, XON1, XON2) - Write Only

These registers are used as the programmable software flow control characters xoff1, xoff2, xon1, and xon2. For more details, refer to **"Section 2.12, Auto Xon/Xoff (Software) Flow Control" on page 11**.

TABLE 11: UART RESET CONDITIONS FOR CHANNEL A AND B

REGISTERS	RESET STATE
DLM and DLL	Bits 15-0 = 0x0001. Resets upon power up only and not when only the Reset Pin is asserted.
RHR	Bits 7-0 = 0xXX
THR	Bits 7-0 = 0xXX
IER	Bits 7-0 = 0x00
FCR	Bits 7-0 = 0x00
ISR	Bits 7-0 = 0x01
LCR	Bits 7-0 = 0x00
MCR	Bits 7-0 = 0x00
LSR	Bits 7-0 = 0x60
MSR	Bits 7-0 = 0x00
SPR	Bits 7-0 = 0xFF
EFR	Bits 7-0 = 0x00
XON1	Bits 7-0 = 0x00
XON2	Bits 7-0 = 0x00
XOFF1	Bits 7-0 = 0x00
XOFF2	Bits 7-0 = 0x00
I/O SIGNALS	**RESET STATE**
TX	RS-232 LOW or +5V
INT	Three-State Condition

ABSOLUTE MAXIMUM RATINGS

Power Supply Range	7 Volts
Voltage at Any Pin	GND-0.3 V to 7 V
Operating Temperature	-40^{o} to +85^{o}C
Storage Temperature	-65^{o} to +150^{o}C
Package Dissipation	500 mW

TYPICAL PACKAGE THERMAL RESISTANCE DATA (MARGIN OF ERROR: ± 15%)

Thermal Resistance (32-QFN)	theta-ja = 33^{o}C/W, theta-jc = 22^{o}C/W

ELECTRICAL CHARACTERISTICS

UNLESS OTHERWISE NOTED: TA= - 40 TO + 85 (INDUSTRIAL GRADE), VCC= 3.0 - 5.5V

SYMBOL	PARAMETER	3.3V LIMITS MIN	3.3V LIMITS MAX	5.0V LIMITS MIN	5.0V LIMITS MAX	UNITS	CONDITIONS

REVISION HISTORY

DATE	REVISION	DESCRIPTION
January 2006	P1.0.0	Preliminary Datasheet
March 2006	P1.0.1	Clarified Partial Sleep Mode and Full Sleep Mode descriptions. Ordering part number changed to XR19L200IL32
April 2006	P1.0.2	Removed "Wireless Portable Devices" from list of applications since the XR19L200 does not have infrared mode.
October 2006	1.0.0	Final Datasheet. Updated DC Electrical Characteristics.
May 2007	1.0.1	Modified "GND Center Pad" to pin description. Updated 32-pin QFN package dimensions drawing to show minimum "k" parameter.
July 2007	1.0.2	Corrected IEC spec # on page 1.

Datasheet July 2007.
