Architecture

The CY7C024E and CY7C025E/CY7C0251E consist of an array of 4K words of 16 bits each and 8K words of 16/18 bits each of dual-port RAM cells, I/O and address lines, and control signals ($\overline{CE}$, $\overline{OE}$, R/$\overline{W}$). These control pins permit independent access for reads or writes to any location in memory. To handle simultaneous writes/reads to the same location, a BUSY pin is provided on each port. Two interrupt ($\overline{INT}$) pins can be used for port-to-port communication. Two semaphore ($\overline{SEM}$) control pins are used for allocating shared resources. With the M/$\overline{S}$ pin, the CY7C024E and CY7C025E/CY7C0251E can function as a master ($\overline{BUSY}$ pins are outputs) or as a slave ($\overline{BUSY}$ pins are inputs). The CY7C024E and CY7C025E/CY7C0251E have an automatic power-down feature controlled by $\overline{CE}$. Each port is provided with its own output enable control ($\overline{OE}$), which allows data to be read from the device.

Functional Overview

Write Operation

Data must be set up for a duration of t_{SD} before the rising edge of R/$\overline{W}$ to guarantee a valid write. A write operation is controlled by either the R/$\overline{W}$ pin (see Figure 7) or the $\overline{CE}$ pin (see Figure 8). Required inputs for non-contention operations are summarized in Table 1.

If a location is being written to by one port and the opposite port attempts to read that location, a port-to-port flowthrough delay must occur before the data is read on the output; otherwise the data read is not deterministic. Data is valid on the port t_{DDD} after the data is presented on the other port.

Read Operation

When reading the device, the user must assert both the $\overline{OE}$ and $\overline{CE}$ pins. Data is available t_{ACE} after $\overline{CE}$ or t_{DOE} after $\overline{OE}$ is asserted. If the user of the CY7C024E and CY7C025E/CY7C0251E wishes to access a semaphore flag, then the SEM pin must be asserted instead of the $\overline{CE}$ pin, and $\overline{OE}$ must also be asserted.

Interrupts

The upper two memory locations may be used for message passing. The highest memory location (FFF for the CY7C024E, 1FFF for the CY7C025E/CY7C0251E) is the mailbox for the right port and the second-highest memory location (FFE for the CY7C024E, 1FFE for the CY7C025E/CY7C0251E) is the mailbox for the left port. When one port writes to the other port's mailbox, an interrupt is generated to the owner. The interrupt is reset when the owner reads the contents of the mailbox. The message is user-defined.

Each port can read the other port's mailbox without resetting the interrupt. The active state of the $\overline{BUSY}$ signal (to a port) prevents the port from setting the interrupt to the winning port. Also, an active $\overline{BUSY}$ to a port prevents that port from reading its own mailbox and thus resetting the interrupt to it.

If your application does not require message passing, do not connect the interrupt pin to the processor's interrupt request input pin.

The operation of the interrupts and their interaction with Busy are summarized in Table 2.

13. If $\overline{BUSY}_R$ = L, then no change.

Busy

The CY7C024E and CY7C025E/CY7C0251E provide on-chip arbitration to resolve simultaneous memory location access (contention). If both ports' $\overline{CE}$s are asserted and an address match occurs within t_{PS} of each other, the busy logic determines which port has access. If t_{PS} is violated, one port definitely gains permission to the location, but which one is not predictable. $\overline{BUSY}$ is asserted t_{BLA} after an address match or t_{BLC} after $\overline{CE}$ is taken LOW.

Master/Slave

A M/$\overline{S}$ pin is provided to expand the word width by configuring the device as either a master or a slave. The $\overline{BUSY}$ output of the master is connected to the $\overline{BUSY}$ input of the slave. This allows the device to interface to a master device with no external components. Writing to slave devices must be delayed until after the $\overline{BUSY}$ input has settled (t_{BLC} or t_{BLA}). Otherwise, the slave chip may begin a write cycle during a contention situation. When tied HIGH, the M/$\overline{S}$ pin allows the device to be used as a master and, therefore, the $\overline{BUSY}$ line is an output. $\overline{BUSY}$ can then be used to send the arbitration outcome to a slave.

Semaphore Operation

The CY7C024E and CY7C025E/CY7C0251E provide eight semaphore latches, which are separate from the dual-port memory locations. Semaphores are used to reserve resources that are shared between the two ports. The state of the semaphore indicates that a resource is in use. For example, if the left port wants to request a given resource, it sets a latch by writing a zero to a semaphore location. The left port then verifies its success in setting the latch by reading it. After writing to the semaphore, $\overline{SEM}$ or $\overline{OE}$ must be deasserted for t_{SOP} before attempting to read the semaphore. The semaphore value is available $t_{SWRD} + t_{DOE}$ after the rising edge of the semaphore write. If the left port was successful (reads a zero), it assumes control of the shared resource, otherwise (reads a one) it assumes the right port has control and continues to poll the semaphore. When the right side has relinquished control of the semaphore (by writing a one), the left side succeeds in gaining control of the semaphore. If the left side no longer requires the semaphore, a one is written to cancel its request.

Semaphores are accessed by asserting $\overline{SEM}$ LOW. The $\overline{SEM}$ pin functions as a chip select for the semaphore latches ($\overline{CE}$ must remain HIGH during $\overline{SEM}$ LOW). $A_{0–2}$ represents the semaphore address. $\overline{OE}$ and R/$\overline{W}$ are used in the same manner as a normal memory access. When writing or reading a semaphore, the other address pins have no effect.

When writing to the semaphore, only I/O_0 is used. If a zero is written to the left port of an available semaphore, a one appears at the same semaphore address on the right port. That semaphore can now only be modified by the side showing zero (the left port in this case). If the left port now relinquishes control by writing a one to the semaphore, the semaphore is set to one for both sides. However, if the right port had requested the semaphore (written a zero) while the left port had control, the right port immediately owns the semaphore as soon as the left port releases it. Table 3 shows sample semaphore operations.

When reading a semaphore, all 16/18 data lines output the semaphore value. The read value is latched in an output register to prevent the semaphore from changing state during a write from the other port. If both ports attempt to access the semaphore within t_{SPS} of each other, the semaphore is definitely obtained by one side or the other, but there is no guarantee which side controls the semaphore.

Table 3. Semaphore Operation Example

Function	I/O_0–$I/O_{15/17}$ Left	I/O_0–$I/O_{15/17}$ Right	Status

Data Retention Mode

The CY7C024E is designed with battery backup in mind. Data retention voltage and supply current are guaranteed over temperature. The following rules insure data retention:

1. Chip enable ($\overline{CE}$) must be held HIGH during data retention, within V_{CC} to V_{CC} – 0.2 V.
2. $\overline{CE}$ must be kept between V_{CC} – 0.2 V and 70% of V_{CC} during the power up and power down transitions.
3. The RAM can begin operation >t_{RC} after V_{CC} reaches the minimum operating voltage (4.5 V).

Notes
17. Tested initially and after any design or process changes that may affect these parameters.
18. $\overline{CE}$ = V_{CC}, V_{in} = GND to V_{CC}, T_A = 25°C. This parameter is guaranteed but not tested.

Notes
30. R/$\overline{W}$ is HIGH for read cycles.
31. Device is continuously selected $\overline{CE}$ = V_{IL} and $\overline{UB}$ or $\overline{LB}$ = V_{IL}. This waveform cannot be used for semaphore reads.
32. $\overline{OE}$ = V_{IL}.
33. Address valid prior to or coincident with $\overline{CE}$ transition LOW.
34. To access RAM, $\overline{CE}$ = V_{IL}, $\overline{UB}$ or $\overline{LB}$ = V_{IL}, $\overline{SEM}$ = V_{IH}. To access semaphore, $\overline{CE}$ = V_{IH}, $\overline{SEM}$ = V_{IL}.

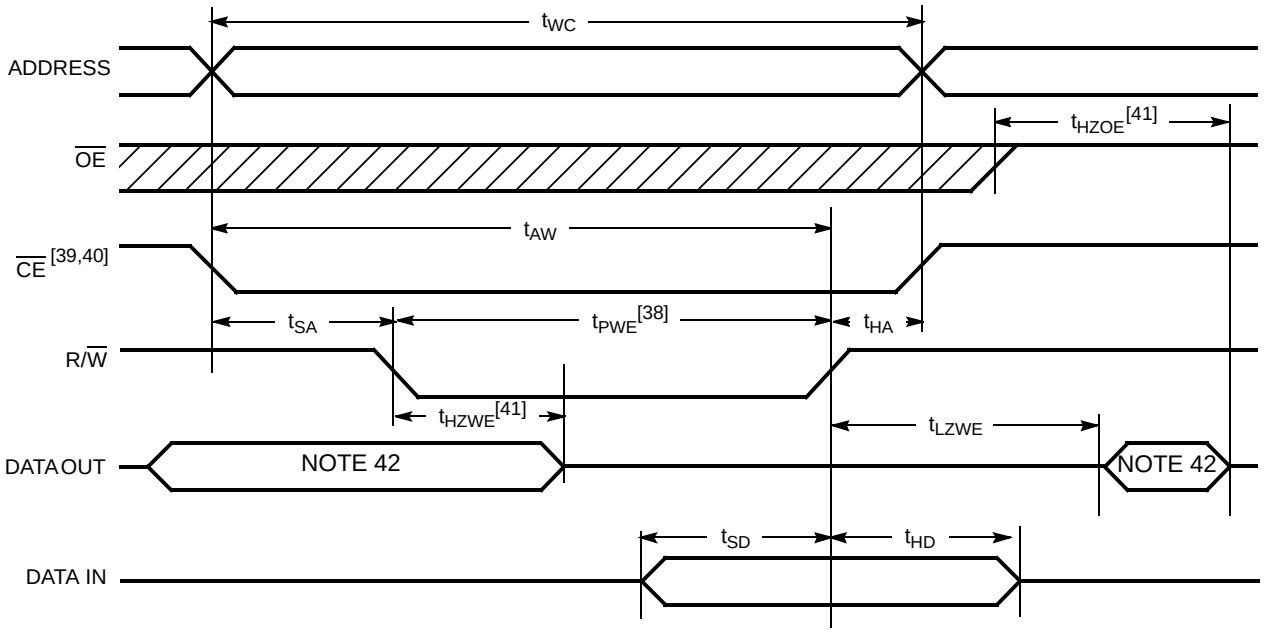

Figure 8. Write Cycle No. 2 ($\overline{CE}$ Controlled Timing) [35, 36, 37, 43]

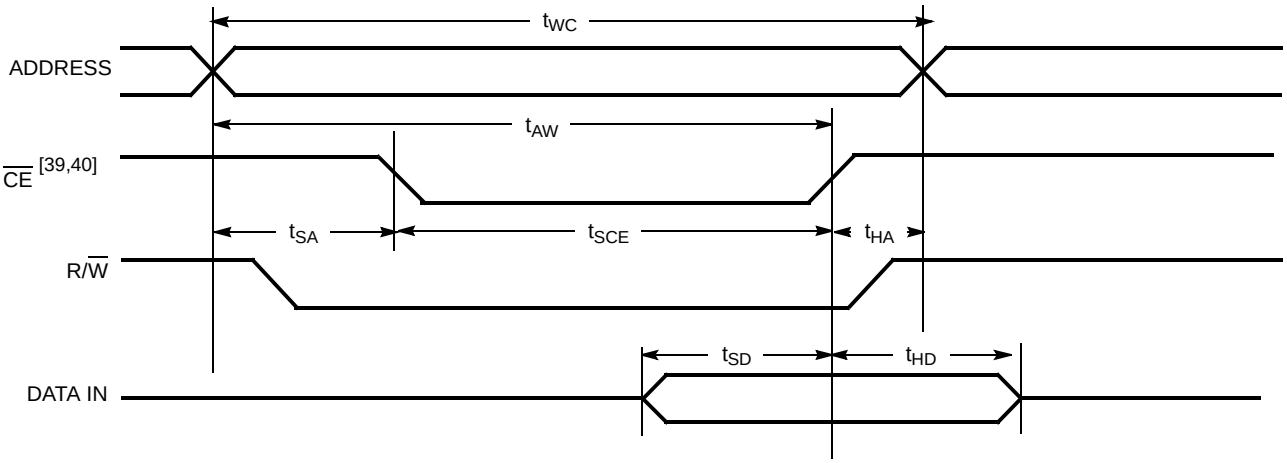

Notes

35. R/$\overline{W}$ must be HIGH during all address transitions.
36. A write occurs during the overlap (t_{SCE} or t_{PWE}) of a LOW $\overline{CE}$ or $\overline{SEM}$ and a LOW $\overline{UB}$ or $\overline{LB}$.
37. t_{HA} is measured from the earlier of $\overline{CE}$ or R/$\overline{W}$ or ($\overline{SEM}$ or R/$\overline{W}$) going HIGH at the end of write cycle.
38. If $\overline{OE}$ is LOW during a R/$\overline{W}$ controlled write cycle, the write pulse width must be the larger of t_{PWE} or ($t_{HZWE} + t_{SD}$) to allow the I/O drivers to turn off and data to be placed on the bus for the required t_{SD}. If $\overline{OE}$ is HIGH during an R/$\overline{W}$ controlled write cycle, this requirement does not apply and the write pulse can be as short as the specified t_{PWE}.
39. To access RAM, $\overline{CE}$ = V_{IL}, $\overline{SEM}$ = V_{IH}.
40. To access upper byte, $\overline{CE}$ = V_{IL}, $\overline{UB}$ = V_{IL}, $\overline{SEM}$ = V_{IH}.
    To access lower byte, $\overline{CE}$ = V_{IL}, $\overline{LB}$ = V_{IL}, $\overline{SEM}$ = V_{IH}.
41. Transition is measured ±500 mV from steady state with a 5 pF load (including scope and jig). This parameter is sampled and not 100% tested.
42. During this period, the I/O pins are in the output state, and input signals must not be applied.
43. If the $\overline{CE}$ or $\overline{SEM}$ LOW transition occurs simultaneously with or after the R/$\overline{W}$ LOW transition, the outputs remain in the high impedance state.

Notes
44. $\overline{CE}$ = HIGH for the duration of the above timing (both write and read cycle).
45. $I/O_{0R} = I/O_{0L}$ = LOW (request semaphore); $\overline{CE}_R = \overline{CE}_L$ = HIGH.
46. Semaphores are reset (available to both ports) at cycle start.

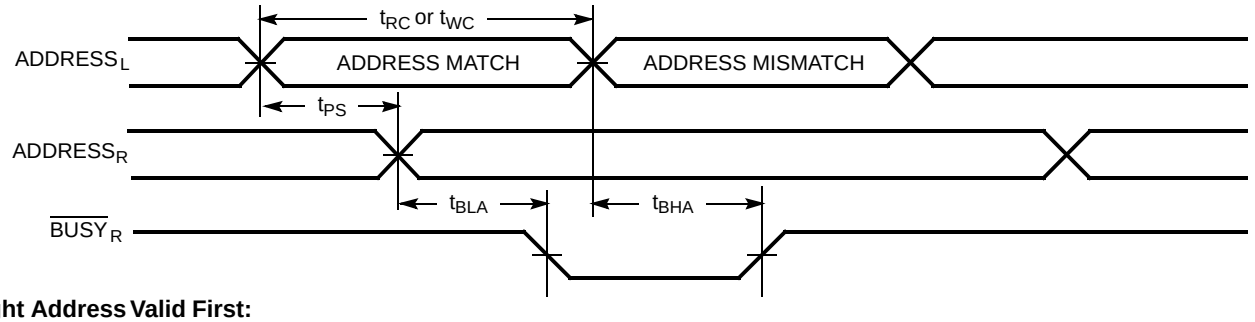
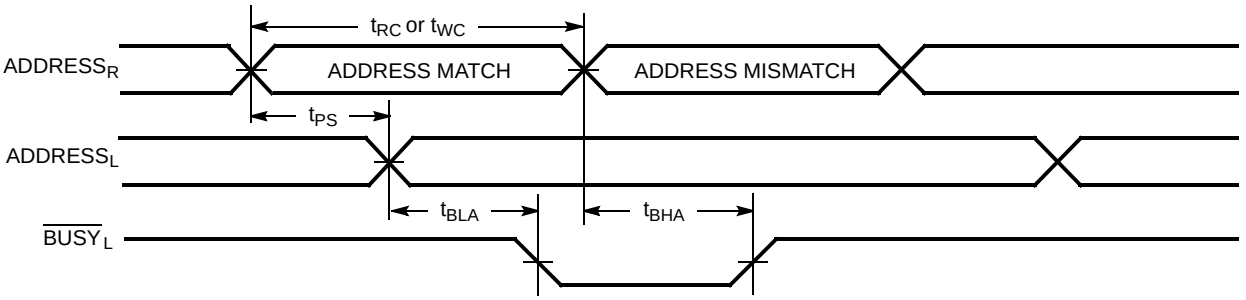
Left Address Valid First:



Right Address Valid First:



Note
49. If t_{PS} is violated, the busy signal is asserted on one side or the other, but there is no guarantee to which side $\overline{BUSY}$ is asserted.

Notes
50. t_{HA} depends on which enable pin ($\overline{CE}_L$ or $R/\overline{W}_L$) is deasserted first.
51. t_{INS} or t_{INR} depends on which enable pin ($\overline{CE}_L$ or $R/\overline{W}_L$) is asserted last.

**	2975554	RAME	07/09/2010	New data sheet.
*A	3056347	ADMU	10/28/2010	Updated Selection Guide: Changed Typical Operating current (mA) from 180 mA to 170 mA (corresponding to speed bin -25). Changed Typical standby current for I_{SB1} (mA) from 45 mA to 40 mA (corresponding to speed bin -25). Changed Typical Operating current (mA) from 180 mA to 150 mA (corresponding to speed bin -55). Changed Typical standby current for I_{SB1} (mA) from 45 mA to 20 mA (corresponding to speed bin -55). Updated Electrical Characteristics: Separated values corresponding to speed bins -25 and -55 into two separate columns. Changed typical value of I_{CC} parameter from 180 mA to 170 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed maximum value of I_{CC} parameter from 275 mA to 250 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed typical value of I_{CC} parameter from 180 mA to 150 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed maximum value of I_{CC} parameter from 275 mA to 230 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed typical value of I_{SB1} parameter from 45 mA to 40 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed maximum value of I_{SB1} parameter from 65 mA to 60 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed typical value of I_{SB1} parameter from 45 mA to 20 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed maximum value of I_{SB1} parameter from 65 mA to 50 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed typical value of I_{SB2} parameter from 110 mA to 100 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed maximum value of I_{SB2} parameter from 160 mA to 150 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed typical value of I_{SB2} parameter from 110 mA to 75 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed maximum value of I_{SB2} parameter from 160 mA to 135 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed typical value of I_{SB4} parameter from 100 mA to 90 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed maximum value of I_{SB4} parameter from 140 mA to 130 mA (corresponding to speed bin -25 and test condition “Commercial”). Changed typical value of I_{SB4} parameter from 100 mA to 70 mA (corresponding to speed bin -55 and test condition “Commercial”). Changed maximum value of I_{SB4} parameter from 140 mA to 120 mA (corresponding to speed bin -55 and test condition “Commercial”). Updated Ordering Information: Updated part numbers.
*B	3247559	ADMU	05/04/2011	Updated Electrical Characteristics: Removed minimum value of V_{IL} parameter (for all speed bins). Updated Ordering Code Definitions under Ordering Information. Updated Package Diagrams: spec 51-85048 – Changed revision from *D to *E.
