Pin Description

| PIN	NAME	FUNCTION
1	FB	Dual-Mode Feedback Input. Connect to GND for the preset 3.3V (MAX183_EUT33) or 5.0V (MAX183_EUT50) output. Connect to a resistive divider between the output and FB to adjust the output voltage between 1.25V and V_{IN}, and connect the OUT pin to GND. When setting output voltages above 5.5V, permanently connect $\overline{SHDN}$ to IN.
2	GND	Ground
3	IN	Input Voltage. 4.5V to 24V input range. Connected to the internal p-channel power MOSFET's source.
4	LX	Inductor Connection. Connected to the internal p-channel power MOSFET's drain.
5	$\overline{SHDN}$	Shutdown Input. A logic-low shuts down the MAX1836/MAX1837 and reduces supply current to 3µA. LX is high impedance in shutdown. Connect to IN for normal operation. When setting output voltages above 5.5V, permanently connect $\overline{SHDN}$ to IN.
6	OUT	Regulated Output Voltage High-Impedance Sense Input. Internally connected to a resistive divider. Connect to the output when using the preset output voltage. Connect to GND when using an external resistive divider to adjust the output voltage.
—	EP	Exposed Metal Pad. Connect to GND. This pad is internally connected to GND through a soft connect. For proper grounding and good thermal dissipation. Connect the exposed pad to GND.
Figure 1. Typical MAX1836 Application Circuit

Figure 2. Typical MAX1837 Application Circuit

Detailed Description

The MAX1836/MAX1837 step-down converters are designed primarily for battery-powered devices, notebook computers, and industrial control applications. A unique current-limited control scheme provides high efficiency over a wide load range. Operation up to 100% duty cycle allows the lowest possible dropout voltage, increasing the useable supply voltage range. Under no-load, the MAX1836/MAX1837 draw only 12µA, and in shutdown mode, they draw only 3µA to further reduce power consumption and extend battery life. Additionally, an internal 24V switching MOSFET, internal current sensing, and a high switching frequency minimize PC board space and component cost.

Current-Limited Control Architecture

The MAX1836/MAX1837 use a proprietary current-limited control scheme that operates with duty cycles up to 100%. These DC-DC converters pulse as needed to maintain regulation, resulting in a variable switching frequency that increases with the load. This eliminates the high supply currents associated with conventional constant-frequency pulse-width-modulation (PWM) controllers that switch the MOSFET unnecessarily.
Figure 3. Functional Diagram

When the output voltage is too low, an error comparator sets a flip-flop, which turns on the internal p-channel MOSFET and begins a switching cycle (Figure 3). As shown in Figure 4, the inductor current ramps up linearly, charging the output capacitor and servicing the load. The MOSFET turns off when the current limit is reached, or when the maximum on-time is exceeded while the output voltage is in regulation. Otherwise, the MOSFET remains on, allowing a duty cycle up to 100% to ensure the lowest possible dropout voltage. Once the MOSFET turns off, the flip-flop resets, diode D1 turns on, and the current through the inductor ramps back down, transferring the stored energy to the output capacitor and load. The MOSFET remains off until the 0.5µs minimum off-time expires and the inductor current ramps down to zero, and the output voltage drops back below the set point.

Figure 4. Discontinuous-Conduction Operation

Input-Output (Dropout) Voltage

A step-down converter's minimum input-to-output voltage differential (dropout voltage) determines the lowest useable input supply voltage. In battery-powered systems, this limits the useful end-of-life battery voltage. To maximize battery life, the MAX1836/MAX1837 operate with duty cycles up to 100%, which minimizes the input-to-output voltage differential. When the supply voltage approaches the output voltage, the P-channel MOSFET remains on continuously to supply the load.

Dropout voltage is defined as the difference between the input and output voltages when the input is low enough for the output to drop out of regulation. For a step-down converter with 100% duty cycle, the dropout voltage depends on the MOSFET drain-to-source on-resistance ($R_{DS(ON)}$) and inductor series resistance; therefore, it is proportional to the load current:

$$V_{DROPOUT} = I_{OUT} \times \left(R_{DS(ON)} + R_{INDUCTOR} \right)$$

Shutdown ($\overline{SHDN}$)

A logic-level low voltage on $\overline{SHDN}$ shuts down the MAX1836/MAX1837. When shut down, the supply current drops to 3µA to maximize battery life, and the internal P-channel MOSFET turns off to isolate the output from the input. The output capacitance and load current determine the rate at which the output voltage decays. A logic-level high voltage on $\overline{SHDN}$ activates the MAX1836/MAX1837. Do not leave $\overline{SHDN}$ floating. If unused, connect $\overline{SHDN}$ to IN. When setting output voltages above 5.5V, the shutdown feature cannot be used, so $\overline{SHDN}$ must be permanently connected to IN. The $\overline{SHDN}$ input voltage slew rate must be greater than 10V/ms.

Thermal-Overload Protection

Thermal-overload protection limits total power dissipation in the MAX1836/MAX1837. When the junction temperature exceeds T_J = +160°C, a thermal sensor turns off the pass transistor, allowing the IC to cool. The thermal sensor turns the pass transistor on again after the IC's junction temperature cools by 10°C, resulting in a pulsed output during continuous thermal-overload conditions.

Design Information

Output Voltage Selection

The feedback input features dual-mode operation. Connect the output to OUT and FB to GND for the preset output voltage. The MAX1836/MAX1837 are supplied with factory-set output voltages of 3.3V or 5V. The two-digit part number suffix identifies the output voltage. See the *Selector Guide*. For example, the MAX1836EUT33 has a preset 3.3V output voltage.

The MAX1836/MAX1837 output voltage may be adjusted by connecting a voltage divider from the output to FB (Figure 5). When externally adjusting the output voltage, connect OUT to GND. Select R2 in the 10kΩ to 100kΩ range. Calculate R1 with the following equation:

$$R1 = R2 \left[\left(\frac{V_{OUT}}{V_{FB}} \right) - 1 \right]$$

where V_{FB} = 1.25V, and V_{OUT} may range from 1.25V to V_{IN}. When setting output voltages above 5.5V, the shutdown feature cannot be used, so $\overline{SHDN}$ must be permanently connected to IN.

Inductor Selection

When selecting the inductor, consider these four parameters: inductance value, saturation current rating, series resistance, and size. The MAX1836/MAX1837 operate with a wide range of inductance values. For most applications, values between 10µH and 100µH work best with the controller's switching frequency. Calculate the minimum inductance value as follows:

$$L_{(MIN)} = \frac{\left(V_{IN(MAX)} - V_{OUT} \right) t_{ON(MIN)}}{I_{LIM}}$$

where $t_{ON(MIN)}$ = 1.0µs. Inductor values up to six times $L_{(MIN)}$ are acceptable. Low-value inductors may be smaller in physical size and less expensive, but they result in higher peak-current overshoot due to current-sense comparator propagation delay (300ns). Peak-current overshoot reduces efficiency and could exceed the current ratings of the internal switching MOSFET and external components.

NOTE: HIGH-CURRENT PATHS SHOWN WITH BOLD LINES.

Figure 5. Adjustable Output Voltage

The inductor's saturation current rating must be greater than the peak switching current, which is determined by the switch current limit plus the overshoot due to the 300ns current-sense comparator propagation delay:

$$I_{PEAK} = I_{LIM} + \frac{(V_{IN} - V_{OUT})300ns}{L}$$

where the switch current-limit (I_{LIM}) is typically 312mA (MAX1836) or 625mA (MAX1837). Saturation occurs when the inductor's magnetic flux density reaches the maximum level the core can support, and the inductance starts to fall.

Inductor series resistance affects both efficiency and dropout voltage. See the *Input-Output (Dropout) Voltage* section. High series resistance limits the maximum current available at lower input voltages and increases the drop-out voltage. For optimum performance, select an inductor with the lowest possible DC resistance that fits in the allotted dimensions. Typically, the inductor's series resistance should be significantly less than that of the internal P-channel MOSFET's on-resistance (1.1Ω typ). Inductors with a ferrite core, or equivalent, are recommended.

The maximum output current of the MAX1836/MAX1837 current-limited converter is limited by the peak inductor current. For the typical application, the maximum output current is approximately:

$$I_{OUT(MAX)} \quad - I_{PEAK}$$

Output Capacitor

Choose the output capacitor to supply the maximum load current with acceptable voltage ripple. The output ripple has two components: variations in the charge stored in the output capacitor with each LX pulse, and the voltage drop across the capacitor's equivalent series resistance (ESR) caused by the current into and out of the capacitor:

$$V_{RIPPLE} \approx V_{RIPPLE(ESR)} + V_{RIPPLE(C)}$$

The output voltage ripple as a consequence of the ESR and output capacitance is:

$$V_{RIPPLE(ESR)} = I_{PEAK}ESR$$

$$V_{RIPPLE(C)} = \frac{L(I_{PEAK} - I_{OUT})^2}{2C_{OUT}V_{OUT}}\left(\frac{V_{IN}}{V_{IN} - V_{OUT}}\right)$$

where I_{PEAK} is the peak inductor current. See the *Inductor Selection* section. These equations are suitable for initial capacitor selection, but final values should be set by testing a prototype or evaluation circuit. As a general rule, a smaller amount of charge delivered in each pulse results in less output ripple. Since the amount of charge delivered in each oscillator pulse is determined by the inductor value and input voltage, the voltage ripple increases with larger inductance but decreases with lower input voltages.

With low-cost aluminum electrolytic capacitors, the ESR-induced ripple can be larger than that caused by the current into and out of the capacitor. Consequently, high-quality low-ESR aluminum-electrolytic, tantalum, polymer, or ceramic filter capacitors are required to minimize output ripple. Best results at reasonable cost are typically achieved with an aluminum-electrolytic capacitor in the 100μF range, in parallel with a 0.1μF ceramic capacitor.

Input Capacitor

The input filter capacitor reduces peak currents drawn from the power source and reduces noise and voltage ripple on the input caused by the circuit's switching. The input capacitor must meet the ripple-current requirement (I_{RMS}) imposed by the switching currents defined by the following equation:

$$I_{RMS} = I_{LOAD}\frac{\sqrt{V_{OUT}(V_{IN} - V_{OUT})}}{V_{IN}}$$

For most applications, nontantalum chemistries (ceramic, aluminum, polymer, or OS-CON) are preferred due to their robustness with high inrush currents typical of systems with low-impedance battery inputs. Alternatively, two (or more) smaller-value low-ESR capacitors can be connected in parallel for lower cost. Choose an input capacitor that exhibits < +10°C temperature rise at the RMS input current for optimal circuit longevity.

Diode Selection

The current in the external diode (D1) changes abruptly from zero to its peak value each time the LX switch turns off. To avoid excessive losses, the diode must have a fast turn-on time and a low forward voltage. Use a diode with an RMS current rating of 0.5A or greater, and with a breakdown voltage > V_{IN}. Schottky diodes are preferred. For high-temperature applications, Schottky diodes may be inadequate due to their high leakage currents. In such cases, ultra-high-speed silicon rectifiers are recommended, although a Schottky diode with a higher reverse voltage rating can often provide acceptable performance.

MAX1836/MAX1837 Stability

Commonly, instability is caused by excessive noise on the feedback signal or ground due to poor layout or improper component selection. When seen, instability typically manifests itself as "motorboating," which is characterized by grouped switching pulses with large gaps and excessive low-frequency output ripple during no-load or light-load conditions.

PC Board Layout and Grounding

High switching frequencies and large peak currents make PC board layout an important part of the design. Poor layout may introduce switching noise into the feedback path, resulting in jitter, instability, or degraded performance. High-power traces, bolded in the typical application circuits (Figure 1 and Figure 2), should be as short and wide as possible. Additionally, the current loops formed by the power components (C_{IN}, C_{OUT}, L1, and D1) should be as tight as possible to avoid radiated noise. Connect the ground pins of these power components at a common node in a star-ground configuration. Separate the noisy traces, such as the LX node, from the feedback network with grounded copper. Furthermore, keep the extra copper on the board, and integrate it into a pseudoground plane. When using external feedback, place the resistors as close to the feedback pin as possible to minimize noise

coupling. The MAX1837 evaluation kit shows the recommended layout.

Applications Information

High-Voltage Step-Down Converter

The typical application circuits' (Figure 1 and Figure 2) components were selected for 9V battery applications. However, the MAX1836/MAX1837 input voltage range allows supply voltages up to 24V. Figure 6 shows a modified application circuit for high-voltage applications. When using higher input voltages, verify that the input capacitor's voltage rating exceeds $V_{IN(MAX)}$ and that the inductor value exceeds the minimum inductance recommended in the *Inductor Selection* section.

Inverter Configuration

Figure 7 shows the MAX1836/MAX1837 in a floating ground configuration. By connecting what would normally be the output to the supply-voltage ground, the IC's ground pin is forced to regulate to -5V (MAX183_EUT50) or -3.3V (MAX183_EUT33). Avoid exceeding the maximum ratings of 24V between IN and GND, and 5.5V between OUT and GND. Other negative voltages may be generated by placing a resistive divider across the output capacitor and connecting the tap to FB in the same manner as the normal step-down configuration.
