

#### **Block Diagram**

### **Absolute Maximum Ratings\***

Temperature Under Bias55°C to +125°	
Storage Temperature65°C to +150°C	0
All Input Voltages (including N.C. Pins) with Respect to Ground0.6 V to +6.25	v
All Output Voltages with Respect to Ground0.6 V to Vcc +0.6	٧
Voltage on $\overline{\text{OE}}$ and A9 with Respect to Ground0.6 V to +13.5	٧

\*NOTICE: Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## **Device Operation**

READ: The AT28C16 is accessed like a Static RAM. When  $\overline{CE}$  and  $\overline{OE}$  are low and  $\overline{WE}$  is high, the data stored at the memory location determined by the address pins is asserted on the outputs. The outputs are put in a high impedance state whenever  $\overline{CE}$  or  $\overline{OE}$  is high. This dual line control gives designers increased flexibility in preventing bus contention.

BYTE WRITE: Writing data into the AT28C16 is similar to writing into a Static RAM. A low pulse on the  $\overline{WE}$  or  $\overline{CE}$  input with  $\overline{OE}$  high and  $\overline{CE}$  or  $\overline{WE}$  low (respectively) initiates a byte write. The address location is latched on the last falling edge of  $\overline{WE}$  (or  $\overline{CE}$ ); the new data is latched on the first rising edge. Internally, the device performs a self-clear before write. Once a byte write has been started, it will automatically time itself to completion. Once a programming operation has been initiated and for the duration of twc, a read operation will effectively be a polling operation.

FAST BYTE WRITE: The AT28C16E offers a byte write time of 200 µs maximum. This feature allows the entire device to be rewritten in 0.4 seconds.

DATA POLLING: The AT28C16 provides DATA POLLING to signal the completion of a write cycle. During a write

cycle, an attempted read of the data being written results in the complement of that data for I/O<sub>7</sub> (the other outputs are indeterminate). When the write cycle is finished, true data appears on all outputs.

WRITE PROTECTION: Inadvertent writes to the device are protected against in the following ways. (a) Vcc sense—if Vcc is below 3.8 V (typical) the write function is inhibited. (b) Vcc power on delay—once Vcc has reached 3.8 V the device will automatically time out 5 ms (typical) before allowing a byte write. (c) Write Inhibit—holding any one of  $\overline{OE}$  low,  $\overline{CE}$  high or  $\overline{WE}$  high inhibits byte write cycles.

CHIP CLEAR: The contents of the entire memory of the AT28C16 may be set to the high state by the CHIP CLEAR operation. By setting  $\overline{\text{CE}}$  low and  $\overline{\text{OE}}$  to 12 volts, the chip is cleared when a 10 msec low pulse is applied to  $\overline{\text{WE}}$ .

DEVICE IDENTIFICATION: An extra 32 bytes of  $E^2PROM$  memory are available to the user for device identification. By raising A9 to  $12\pm0.5$  V and using address locations 7E0H to 7FFH the additional bytes may be written to or read from in the same manner as the regular memory array.
