**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into device pins are positive; all currents out of device pins are negative. All voltages are referenced to GND unless otherwise specified.

**Note 3:** LTC4224-2 only.

**Note 4:** The greater of  $V_{CC1}$  and  $V_{CC2}$  is the internal supply voltage ( $V_{CC}$ ). An internal clamp limits the GATE pin to a minimum 5V above  $V_{CC}$ . Driving this pin beyond the clamp may damage the device.

## PIN FUNCTIONS

**SENSE1, SENSE2 (Pins 1, 10):** Current Sense Input. Connect this pin to an external sense resistor. The current limit circuit controls GATEn to limit the voltage between  $V_{CCn}$  and SENSEn to 25mV. An Electronic Circuit Breaker (ECB) is active during current limiting and trips after 5ms. To disable current limit, connect this pin to  $V_{CCn}$ .

**$V_{CC1}$ ,  $V_{CC2}$  (Pins 2, 9):** Supply Voltage and Current Sense Input. An undervoltage lockout circuit disables the part until  $V_{CC}$ , the higher of  $V_{CC1}$  and  $V_{CC2}$ , exceeds 2.4V. The lower supply is disabled until it exceeds 0.8V.

**GATE1, GATE2 (Pins 3, 8):** Gate Drive for External N-channel MOSFET. A charge pump sources 10 $\mu$ A from GATE to turn on the external MOSFET. An internal clamp limits the gate voltage to 5.5V above the higher of  $V_{CC1}$  and  $V_{CC2}$ . During turn-off, a 1.5mA pulldown current discharges GATE to

ground. During short-circuits, a 125mA pulldown current is activated to discharge GATE to ground.

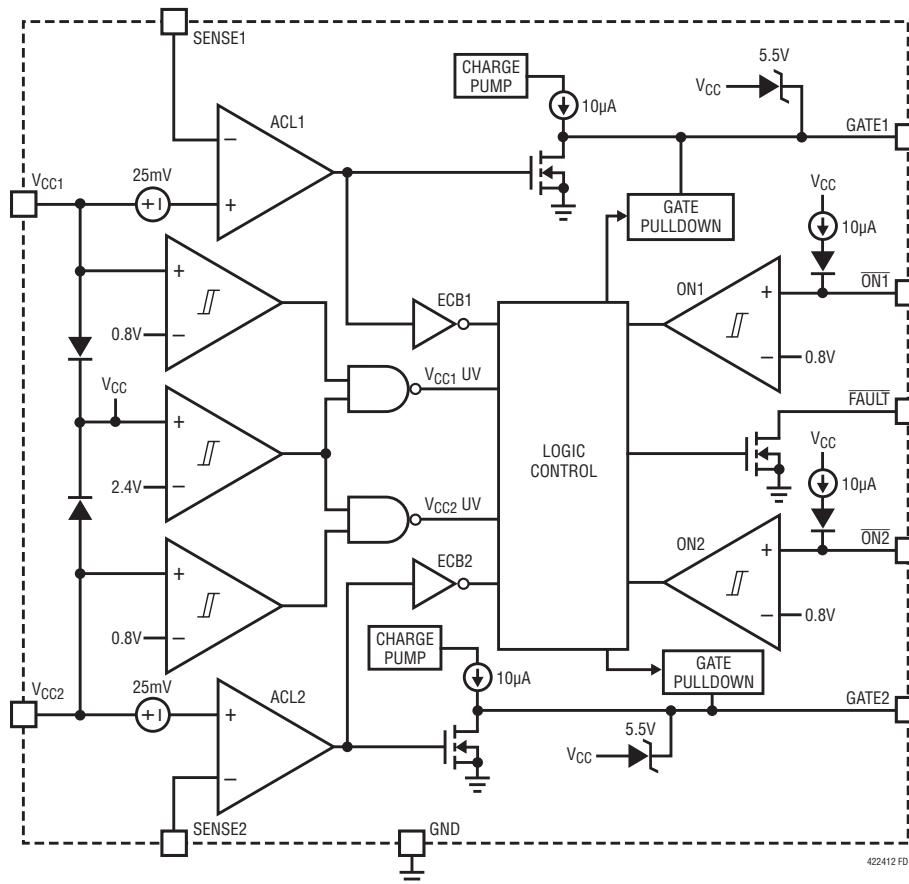

**FAULT (Pin 4):** Fault Status Output. Open-drain output that is normally pulled high to  $V_{CC1}$  or  $V_{CC2}$  by an external resistor. It is pulled low when the ECB trips due to an overcurrent condition at either supply. This pin may be left open if unused.

**ON1, ON2 (Pins 5, 6):** On Control Input. A falling edge turns on the external N-channel MOSFET and a rising edge turns it off. A low to high transition on this pin resets an ECB fault for the corresponding channel. Internally pulled up to  $V_{CC}$  by a 10 $\mu$ A current source.

**GND (Pin 7):** Device Ground.

**Exposed Pad (DFN Package Only):** Exposed Pad may be left open or connected to device ground.

## FUNCTIONAL DIAGRAM

422412fa

## OPERATION

The LTC4224 is designed to control power on a live backplane, allowing boards to be safely inserted and removed. It controls two supplies ( $V_{CC1}$ ,  $V_{CC2}$ ) with operating voltages between 1V and 6V via two external N-channel MOSFETs. For applications where the total load current is 5A or less, dual MOSFETs such as the FDS6911 can be used to save board area. The two supplies can be turned on and off independently using the active low  $\overline{ON1}$  and  $\overline{ON2}$  pins. Internal 10 $\mu$ A current sources pull these pins to  $V_{CC}$ .

Pulling the  $\overline{ON}$  pin low turns on a charge pump which sources 10 $\mu$ A at the GATE pin thereby ramping up the gate of the external MOSFET. When the MOSFET turns on, the inrush current is limited at a level set by an external sense resistor. Inrush current can be further reduced, if desired, by adding a capacitor from GATE to GND. To protect the external MOSFET, the GATE pins are clamped to about 5.5V above the higher of the two supplies.

Each supply is continuously monitored for undervoltage and overcurrent conditions. The undervoltage monitor shuts off the external MOSFET when the corresponding supply is too low.

Current is monitored by an active current limit amplifier (ACL) and a timed electronic circuit breaker (ECB). Like all timing delays in the LTC4224, the ECB delay of 5ms is generated internally without requiring any external timing capacitors. The ECB threshold is slightly below the ACL threshold and shuts off the external MOSFET after 5ms.  $\overline{FAULT}$  is latched low to indicate an overcurrent fault.

The LTC4224-1 remains latched off until reset by either turning off and then on the affected supply or its  $\overline{ON}$  pin. The LTC4224-2 automatically restarts after four seconds to allow time for the MOSFET to cool down.

## APPLICATIONS INFORMATION

The typical LTC4224 application is in a high availability system where two positive supply voltages are distributed to power individual cards. The LTC4224 detects board presence during insertion and removal, allowing power to be delivered in a controlled manner without damaging the connector. It reports overcurrent faults to the system controller through its  $\overline{FAULT}$  pin, which can light an LED or can be monitored by a system controller.

The basic LTC4224 application circuit is shown in Figure 1. The following sections cover  $V_{CC}$  selection, the normal turn-on and turn-off sequence, various fault conditions and recovery from fault situations. External component selection is discussed in detail in the Design Example section.

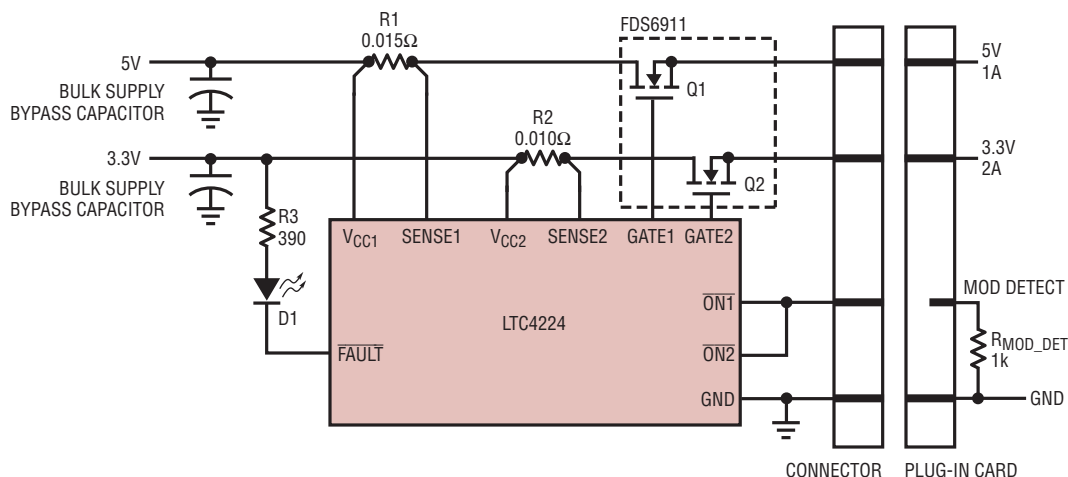

Figure 1. Typical Application

## APPLICATIONS INFORMATION

### V<sub>CC</sub> Selection

The LTC4224 is powered from the higher of its two supply pins, V<sub>CC1</sub> and V<sub>CC2</sub>. This allows the part to control a supply voltage as low as 1V, while the other supply is 2.7V or greater. If both supplies are tied together, the part derives its power from both equally. The Functional Diagram shows the V<sub>CC</sub> selection circuit in an ideal diode OR-ing arrangement. It is designed to ensure swift and smooth internal power switchover from one supply to the other.

### Turn-On Sequence

Separate  $\overline{\text{ON1}}$  and  $\overline{\text{ON2}}$  pins allow the V<sub>CC1</sub> and V<sub>CC2</sub> supplies to be turned on in any order. The power supplies delivered to a plug-in card are controlled by external N-channel MOSFETs, Q1 and Q2. For X2/XENPAK defined optical transceiver modules, it has been specified that the MOD DETECT pin pulls low inside the module through a 1k resistor (R<sub>MOD\_DET</sub>), as shown in Figure 1. Several conditions must be satisfied to turn on the MOSFETs. First, V<sub>CC1</sub> or V<sub>CC2</sub> must exceed the 2.4V V<sub>CC</sub> undervoltage lockout level for longer than an internal UV turn-on delay of 160ms. Next, if V<sub>CCn</sub> is greater than 0.8V and  $\overline{\text{ONn}}$  is low (<0.8V), a debounce delay of 10ms is started. If V<sub>CCn</sub> drops below 0.8V or  $\overline{\text{ONn}}$  goes high before the end of the 10ms debounce delay, the debounce delay is restarted the next time these pins are properly conditioned.

When the 10ms debounce delay expires, the external MOSFET is turned on by charging up the GATE with a

Figure 2. Normal Power-Up Sequence

10μA charge pump generated current source. When the GATE voltage reaches the MOSFET threshold voltage, the inrush current can build up quickly as the GATE continues to rise. The ACL amplifier actively controls the gate voltage to maintain 25mV across the sense resistor. In this condition, the inrush current is given by:

$$I_{\text{INRUSH}} = \frac{25\text{mV}}{R_{\text{SENSE}}}$$

As the inrush current charges up the load capacitor, the output rises with a corresponding increase in gate voltage. When the supply is no longer in current limit, an internal charge pump pulls the gate to 5.5V above the higher of V<sub>CC1</sub> or V<sub>CC2</sub> to achieve a low resistance power path. Figure 2 shows a typical start-up sequence with C<sub>LOAD1</sub> = C<sub>LOAD2</sub> = 150μF, R<sub>LOAD1</sub> = 4.7Ω and R<sub>LOAD2</sub> = 2Ω.

The inrush current can be reduced to below the current limit level by adding an external gate capacitor as shown in Figure 3.

GATE capacitor C<sub>GATE</sub> provides gate slew rate control to limit the inrush current. However, C<sub>GATE</sub> could cause parasitic high frequency self oscillation in Q1. A 10Ω resistor, R<sub>G</sub>, as shown in Figure 3 can be used to prevent the oscillation. To be effective, R<sub>G</sub> needs to be laid out close to Q1.

The voltage at the GATE pin rises with a slope equal to I<sub>GATE</sub>/C<sub>GATE</sub>. For a given supply inrush current I<sub>INRUSH</sub> and load capacitor C<sub>LOAD</sub>, C<sub>GATE</sub> can be calculated according to:

$$C_{\text{GATE}} = \frac{I_{\text{GATE}}}{I_{\text{INRUSH}}} \cdot C_{\text{LOAD}}$$

Figure 3. Inrush Current Control by Gate Capacitor

## APPLICATIONS INFORMATION

If the voltage across the sense resistor R1 becomes too high, the inrush current is limited by the internal current limit circuitry.

### Turn-Off Sequence

The MOSFETs can be turned off by the conditions summarized in Table 1.

**Table 1. Turn-Off Conditions**

CONDITION	RESULT		CLEARED BY
	CHANNEL 1	CHANNEL 2	
$\overline{\text{ON}}1$ Goes High	Turns Off	No Effect	$\overline{\text{ON}}1$ Low
$\overline{\text{ON}}2$ Goes High	No Effect	Turns Off	$\overline{\text{ON}}2$ Low
UVLO on $V_{CC}$	Turns Off	Turns Off	$V_{CC} > \text{UVLO}$
UVLO on $V_{CC1}$	Turns Off	No Effect	$V_{CC1} > \text{UVLO}$
UVLO on $V_{CC2}$	No Effect	Turns Off	$V_{CC2} > \text{UVLO}$
CH1 Overcurrent Fault	Turns Off	No Effect	$\overline{\text{ON}}1$ High, UVLO on $V_{CC1}$
CH2 Overcurrent Fault	No Effect	Turns Off	$\overline{\text{ON}}2$ High, UVLO on $V_{CC2}$

When  $\overline{\text{ON}}1$  or  $\overline{\text{ON}}2$  is pulled high, the corresponding GATE pin is pulled to ground by 1.5mA. With the MOSFET off, the load current discharges the load capacitor. Figure 4 shows  $V_{CC1}$  supply turning off by pulling  $\overline{\text{ON}}1$  high with  $R_{\text{LOAD}1} = 4.7\Omega$  discharging  $C_{\text{LOAD}1} = 150\mu\text{F}$ .

### Overcurrent Fault

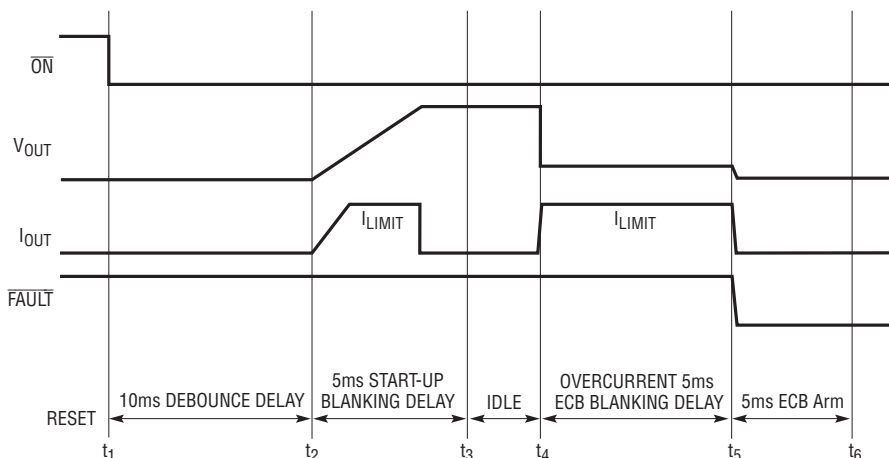

The LTC4224 features an adjustable current limit with circuit breaker function that protects external MOSFETs against short circuits or excessive load current. The voltage across

**Figure 4. Normal Power-Down Sequence**

the external sense resistor is monitored by the active current limit (ACL) amplifier and the electronic circuit breaker (ECB) comparator. An overcurrent condition results in the current being limited by the ACL amplifier. During current limiting, the ECB is activated and initiates a chain of logic and timing events to handle the fault.

Figure 5 illustrates the LTC4224's response to an overcurrent condition on one supply output. Start-up and overcurrent control for the two supplies are independent. Before time point  $t_1$ , the  $\overline{\text{ON}}$  pin is high and the part is in reset. When the  $\overline{\text{ON}}$  pin goes low, a 10ms debounce delay is started. After 10ms (time point  $t_2$ ), the external MOSFET is turned on by charging GATE with  $10\mu\text{A}$ . The load capacitor starts to charge up and the output voltage increases. At the same

**Figure 5. Fault Handling Sequence**

422412 F05

422412fa

## APPLICATIONS INFORMATION

Figure 6. Start-Up with Short at Output

time, a 5ms start-up blanking delay begins during which the circuit breaker is not allowed to latch off the MOSFET. If the ECB is tripped at the end of 5ms (time point  $t_3$ ), the MOSFET is latched off by pulling GATE down with 1.5mA and  $\overline{\text{FAULT}}$  is latched low. The waveform in Figure 6 shows an unsuccessful start-up due to a short circuit at the output. To ensure start-up, the load capacitor must be charged up sufficiently to exit current limit before the end of the 5ms blanking delay. For large load capacitors, it may be necessary to connect an external capacitor from GATE to GND as described in the Turn-On Sequence section.

After start-up, any transient overcurrent faults lasting less than 100 $\mu$ s are ignored. Any overcurrent condition lasting more than 100 $\mu$ s will initiate the 5ms ECB blanking delay (time point  $t_4$ ). After the ECB blanking delay, the ECB is armed for the following 5ms (time point  $t_5$  to  $t_6$ ). Any 100 $\mu$ s overcurrent pulse during this time latches off the MOSFET. In summary, for 5ms to 10ms after a 100 $\mu$ s or greater overcurrent fault is detected, a second 100 $\mu$ s fault condition causes the MOSFET to latch off. If no overcurrent condition is detected during this time, the part re-enters the IDLE state and another blanking delay following an overcurrent condition is again required before the MOSFET latches off. Figure 7 shows how the output latches off following an overcurrent fault.

During a severe short-circuit (see Figure 8), the output load current can briefly surge to tens of amperes. The LTC4224 rapidly brings the current under control by discharging

Figure 7. Overcurrent Fault on Output

Figure 8. Severe Short-Circuit on Output

the MOSFET's gate with 125mA towards ground. After a short delay, the ACL amplifier regulates the gate voltage until the ECB trips at the end of 5ms.

### Undervoltage Fault

An undervoltage fault occurs if either  $V_{CC1}$  or  $V_{CC2}$  falls below 0.8V for longer than 8 $\mu$ s. This turns off the affected supply's switch by discharging GATE with 1.5mA and clears its fault latch. An undervoltage fault on one supply does not affect the operation of the other supply. If  $V_{CC}$ , the higher of  $V_{CC1}$  and  $V_{CC2}$ , falls below 2.4V for more than 12 $\mu$ s, all supply switches are turned off and all fault latches are cleared.

## APPLICATIONS INFORMATION

If there is significant supply lead inductance, a severe output short may collapse the input to ground before the LTC4224 can bring the current under control. In this case, the undervoltage lockout activates after an 8 $\mu$ s filter delay, and the GATE is pulled down by 1.5mA.

### Resetting Faults

Following an overcurrent fault, the LTC4224-1 latches off while the LTC4224-2 automatically restarts after a four second cool down period. An overcurrent fault on either supply causes the ECB for that supply to turn off the MOSFET and pull the  $\overline{\text{FAULT}}$  pin low. Faults are reset by pulling the  $\overline{\text{ON}}$  pin high for at least 20 $\mu$ s, after which the  $\overline{\text{FAULT}}$  pin releases and the turn-on sequence begins. Taking the lower supply below  $V_{\text{CCLO}}(\text{UVL})$  clears only that supply's fault and the turn-on sequence commences immediately. Pulling the higher supply below  $V_{\text{CC}}(\text{UVL})$  clears both supplies' faults and the turn-on sequence begins after a 160ms UV turn-on delay. When both supplies are above 2.5V, either supply going low only resets its own fault.

For the auto-retry version (LTC4224-2), if the fault is not cleared within four seconds, the latched fault will be cleared automatically.  $\overline{\text{FAULT}}$  will go high and the turn-on sequence will begin. A persistent fault results in an auto-retry duty cycle of about 0.1%. Figure 9 shows an auto-retry sequence as a result of an overcurrent fault.

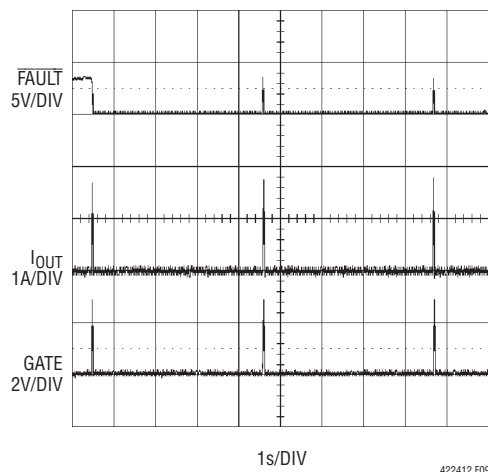

Figure 9. Auto-Retry After Overcurrent Fault

### Gate Pin Voltage

The gate drive is compatible with logic level MOSFETs, but caution is required if one supply is low. The guaranteed range of gate drive is 4.5V to 7V, with a typical value of 5.5V. Each GATE pin is clamped with respect to  $V_{\text{CC}}$ , the higher of the two input supplies. When  $V_{\text{CC}}$  is at 5V, both GATE pins can be as high as 12V above ground. If the lower supply is at 0V, the gate-to-source voltage of its MOSFET can be 12V. In such applications, MOSFETs with gate-to-source breakdown ratings of 12V or greater are recommended.

### Active Current Loop Compensation

The active current loop is compensated by the parasitic capacitance of the external MOSFET. No further compensation components are normally required. In the case where a MOSFET with less than 600pF of gate capacitance is chosen, a 600pF compensation capacitor connected between the GATE pin and ground may be required.

### Supply Transient Protection

In applications where the supply inputs are fed directly from the regulated output of the backplane supply, bulk bypassing assures a spike-free operating environment. In other applications where bulk bypassing is located far from the LTC4224, spikes generated during output short-circuit events could exceed the absolute maximum ratings for  $V_{\text{CC}}$ . To minimize such spikes, use wider traces or heavier trace plating to reduce the power trace inductance.

Figure 10. Input Supply Transient Protection Network for Applications without Input Capacitance

## APPLICATIONS INFORMATION

Figure 11. Recommended Layout for Input Supply Transient Protection Network

Also, bypass locally with a 10 $\mu$ F electrolytic and 100nF ceramic, or alternatively clamp the input with a transient voltage suppressor (Z1) as shown in Figure 10. A 10 $\Omega$ , 100nF snubber damps the response and eliminates ringing. A recommended layout of the transient protection devices Z1,  $R_{SNUB}$  and  $C_{SNUB}$  around the LTC4224 is shown in Figure 11.

## PCB Layout Considerations

For proper operation of the LTC4224's electronic circuit breaker, Kelvin connections to the sense resistors are strongly recommended. The PCB layout should be balanced and symmetrical to minimize wiring errors. In addition, the

Figure 12. Recommended Layout for Power MOSFET and Sense Resistors

PCB layout for the sense resistors and the power MOSFETs should include good thermal management techniques for optimal device power dissipation. A recommended PCB layout for the sense resistors and the power MOSFET around the LTC4224 is illustrated in Figure 12. Note that it is important to keep the trace from the LTC4224's GATE pin to the FDS6911's gate short.

In Hot Swap applications where load currents can be 10A, wide PCB traces are recommended to minimize resistance and temperature rise. The suggested trace width for 1oz copper foil is 0.03" for each ampere of DC current to keep PCB trace resistance, voltage drop and temperature rise to a minimum. Note that the sheet resistance of 1oz copper foil is approximately 0.5m $\Omega$ /square and voltage drops due to trace resistances add up quickly in high current applications.

In most applications, it is necessary to use plated-through vias to make circuit connections from component layers to power and ground layers internal to the PCB. For 1oz copper foil plating, a general rule is 1A of DC current per via. Consult your PCB fabrication facility for design rules pertaining to other plating thicknesses.

## Design Example

As a design example, consider the following specifications:  $V_{CC1} = 5V$ ,  $V_{CC2} = 3.3V$ ,  $I_{LOAD1(MAX)} = 1A$ ,  $I_{LOAD2(MAX)} = 2A$ ,  $C_{LOAD1} = C_{LOAD2} = 150\mu F$  (see Figure 1).

First, select the sense resistor for each supply. Calculate the R1 and R2 values based on the maximum load current and the minimum circuit breaker threshold limit,  $\Delta V_{SENSE(CB)(MIN)}$ .

If a 1% tolerance is assumed for the sense resistors, then the following values of resistance should suffice:

Table 2. Sense Resistor Values

SUPPLY VOLTAGE	$R_{SENSE}$ (1%)	$I_{TRIP(MIN)}$	$I_{TRIP(MAX)}$
5V	15m $\Omega$	1.49A	1.85A
3.3V	10m $\Omega$	2.23A	2.78A

For proper operation,  $I_{TRIP(MIN)}$  must exceed the maximum load current with margin, so  $R_{SENSE1} = 15m\Omega$  and  $R_{SENSE2} = 10m\Omega$  should suffice for the  $V_{CC1}$  and  $V_{CC2}$  supplies respectively.

## APPLICATIONS INFORMATION

Next, assume that there is no load current at start-up, and calculate the inrush current required to charge the load capacitor. As there is no gate capacitor, the supplies start-up in current limit. Compute the time,  $t_{SU}$ , it takes to fully charge the load capacitor:

$$t_{SU} = \frac{V_{CC} \cdot C_{LOAD}}{I_{TRIP}}$$

Table 3 lists the worst-case  $t_{SU}$  values assuming 30% tolerance for load capacitances.

**Table 3. Worst-Case  $t_{SU}$**

VOLTAGE SUPPLY	$t_{SU(MIN)}$	$t_{SU(MAX)}$
5V	0.53ms	0.65ms
3.3V	0.23ms	0.29ms

The start-up ECB blanking delay is guaranteed to be at least 2.5ms, which is longer than the  $t_{SU}$  tabulated in Table 3. Hence, both supplies can start up successfully.

Next, verify that the thermal ratings of the selected external MOSFETs are not exceeded during power-up or an output short-circuit. Assuming the MOSFET dissipates power only due to inrush current charging the load capacitor, the energy dissipated in the MOSFET during power-up is the same as that stored in the load capacitor after power-up. The average power dissipated in the MOSFET is given by:

$$P_{AVG} = \frac{C_{LOAD} \cdot V_{OUT}^2}{2 \cdot t_{SU}}$$

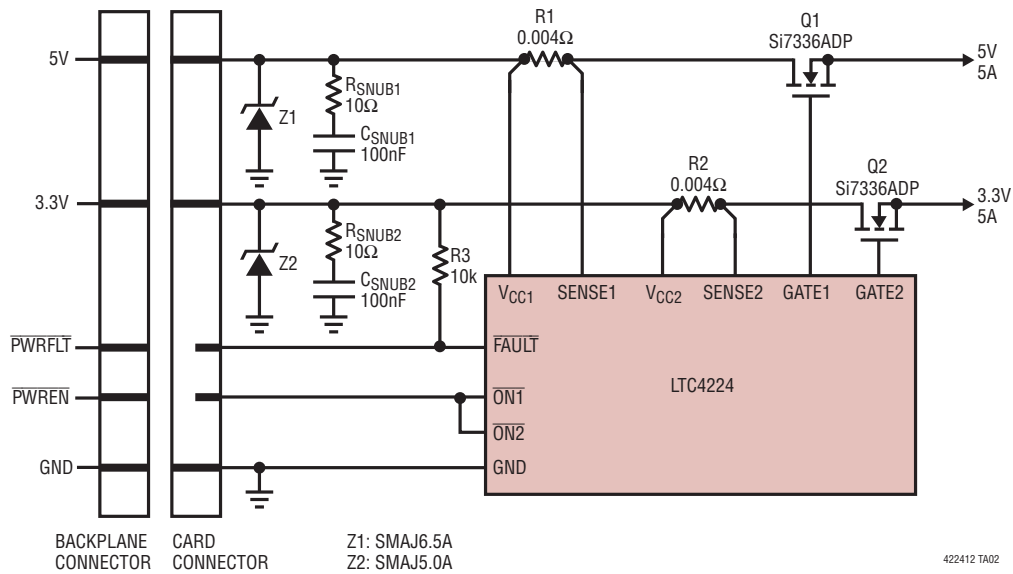

The worst-case  $P_{AVG}$  is calculated to be 4.6W for both the 5V supply and the 3.3V supply. In this example, the FDS6911 MOSFET offers a good solution. Since this MOSFET is a dual N-channel in a single SO8 package, it must be able to tolerate the combined power dissipation of both supplies during the  $t_{SU}$  start-up time. The increase in steady-state junction temperature due to power dissipated in the MOSFET is  $\Delta T = P_{AVG} \cdot Z_{TH}$  where  $Z_{TH}$  is the thermal impedance.

Under this condition, the FDS6911 datasheet's Transient Thermal Impedance plot indicates that the junction temperature will increase by 6.4°C using  $Z_{THJC} = 0.7^\circ\text{C/W}$  (single pulse). The FDS6911's on-resistance is 17mΩ at  $V_{GS} = 4.5\text{V}$ , 25°C.

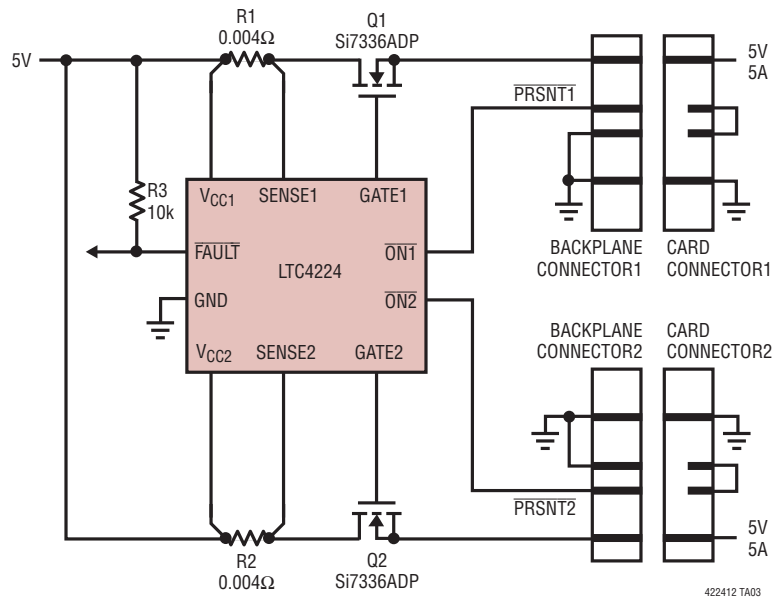

The magnitude of the power pulse that results during a severe overload is calculated to be 9.25W for the 5V supply and 9.2W for the 3.3V supply under the worst case conditions. Assuming a worst-case circuit breaker timeout period of 7.5ms, the junction temperature will increase by 25°C, with one supply short-circuited. If both supplies are short-circuited, the junction temperature will increase by 50°C in the worst-case. During auto-retry (LTC4224-2), in the event of persistent faults at both supplies, the ample four second cooling delay limits the increase in junction temperature to 50°C. The SOA curves of the FDS6911 indicate that the above conditions are safe.

## TYPICAL APPLICATION

## 5V and 3.3V Card Resident Application

## Hot Swap Application for Two Add-In Cards

## PACKAGE DESCRIPTION

**DDB Package**  
**10-Lead Plastic DFN (3mm × 2mm)**  
 (Reference LTC DWG # 05-08-1722)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS

## NOTE:

1. DRAWING CONFORMS TO VERSION (WECD-1) IN JEDEC PACKAGE OUTLINE M0-229
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

## PACKAGE DESCRIPTION

**MS Package**  
**10-Lead Plastic MSOP**  
 (Reference LTC DWG # 05-08-1661)

## NOTE:

1. DIMENSIONS IN MILLIMETER/(INCH)
2. DRAWING NOT TO SCALE
3. DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS.  
MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
4. DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS.  
INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
5. LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.102mm (.004") MAX

# LTC4224-1/LTC4224-2

PART NUMBER	DESCRIPTION	COMMENTS
LTC1421	Two Channel Hot Swap Controller	Operates from 3V to 12V and Supports -12V
LTC1645	Dual Channel Hot Swap Controller	Operates from 3V to 12V, Power Sequencing
LTC1647	Dual Channel Hot Swap Controller	Operates from 2.7V to 16.5V, Separate ON Pins to Sequence
LTC4210	Single Channel Hot Swap Controller	Operates from 2.7V to 16.5V, Active Current Limiting
LTC4211	Single Channel Hot Swap Controller	2.5V to 16.5V, Multifunction Current Control
LTC4212	Single Channel Hot Swap Controller	2.5V to 16.5V, Multifunction Current Control with Power Good Input
LTC4213	Electronic Circuit Breaker	Operates from 2.3V to 6V, No R <sub>SENSE</sub> ™ Electronic Circuit Breaker
LTC4215	Single Channel Hot Swap Controller	Operates from 2.9V to 15V, I <sup>2</sup> C Compatible Monitoring
LTC4216	Single Channel Hot Swap	Operates from 0V to 6V
LTC4218	Single Channel Hot Swap Controller	Operates from 2.9V to 26.5V, Adjustable, 5% Accurate (15mV) Current Limit
LTC4221	Dual Channel Hot Swap Controller	Operates from 1V to 13.5V, Multifunction Current Control
LTC4223	Dual Supply Hot Swap Controller	Controls 12V and 3.3V for AMC and μTCA
