Applications Information

Device Connection Options for Protection of Four High-Speed Lines

The SRDA TVS is designed to protect four data lines from transient overvoltages by clamping them to a fixed reference. When the voltage on the protected line exceeds the reference voltage (plus diode V_F) the steering diodes are forward biased, conducting the transient current away from the sensitive circuitry. Data lines are connected at pins 1, 4, 6 and 7. The negative reference is connected at pins 5 and 8. These pins should be connected directly to a ground plane on the board for best results. The path length is kept as short as possible to minimize parasitic inductance.

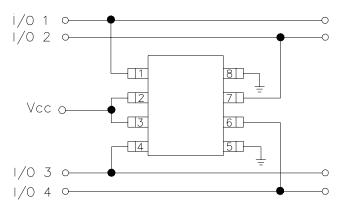

The positive reference is connected at pins 2 and 3. The options for connecting the positive reference are as follows:

- 1. To protect data lines and the power line, connect pins 2 & 3 directly to the positive supply rail (V_{cc}). In this configuration the data lines are referenced to the supply voltage. The internal TVS diode prevents over-voltage on the supply rail.
- 2. The SRDA can be isolated from the power supply by adding a series resistor between pins 2 and 3 and V_{cc} . A value of $10k\Omega$ is recommended. The internal TVS and steering diodes remain biased, providing the advantage of lower capacitance.
- 3. In applications where no positive supply reference is available, or complete supply isolation is desired, the internal TVS may be used as the reference. In this case, pins 2 and 3 are not connected. The steering diodes will begin to conduct when the voltage on the protected line exceeds the working voltage of the TVS (plus one diode drop).

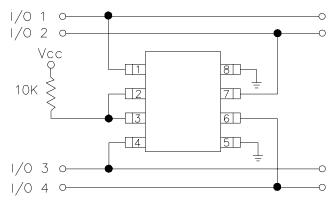

ESD Protection With RailClamps

RailClamps are optimized for ESD protection using the rail-to-rail topology. Along with good board layout, these devices virtually eliminate the disadvantages of using discrete components to implement this topology. Consider the situation shown in Figure 1 where discrete diodes or diode arrays are configured for rail-to-rail protection on a high speed line. During positive duration ESD events, the top diode will be forward biased when the voltage on the protected line exceeds the reference voltage plus the V drop of the diode. For negative events, the bottom ^Fdiode will be biased

Applications Information (continued)

when the voltage exceeds the V of the diode. At first approximation, the clamping voltage due to the characteristics of the protection diodes is given by:

$$V_{c} = V_{cc} + V_{F}$$
 (for positive duration pulses)
 $V_{c} = -V_{F}$ (for negative duration pulses)

However, for fast rise time transient events, the effects of parasitic inductance must also be considered as shown in Figure 2. Therefore, the actual clamping voltage seen by the protected circuit will be:

 $V_{c} = V_{cc} + V_{F} + L_{P} \frac{di}{esd} / dt$ (for positive duration pulses)

 $V_{c} = -V_{F} - L_{G} \frac{di}{ESD} / dt$ (for negative duration pulses)

ESD current reaches a peak amplitude of 30A in 1ns for a level 4 ESD contact discharge per IEC 61000-4-2. Therefore, the voltage overshoot due to 1nH of series inductance is:

$$V = L_{p} \frac{di}{dt} / dt = 1X10^{-9} (30 / 1X10^{-9}) = 30V$$

Example:

Consider a V = 5V, a typical V of 30V (at 30A) for the steering diode and a series trace inductance of 10nH. The clamping voltage seen by the protected IC for a positive 8kV (30A) ESD pulse will be:

$$V_{c} = 5V + 30V + (10nH X 30V/nH) = 335V$$

This does not take into account that the ESD current is directed into the supply rail, potentially damaging any components that are attached to that rail. Also note the high V of the discrete diode. It is not uncommon for the V $\frac{1}{6}$ f discrete diodes to exceed the damage threshold of the protected IC. This is due to the relatively small junction area of typical discrete components. It is also possible that the power dissipation capability of the discrete diode will be exceeded, thus destroying the device.

The RailClamp is designed to overcome the inherent disadvantages of using discrete signal diodes for ESD suppression. The RailClamp's integrated TVS diode helps to mitigate the effects of parasitic inductance in

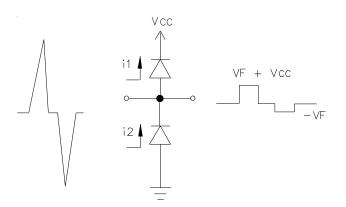

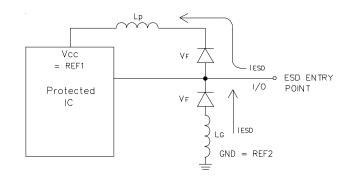

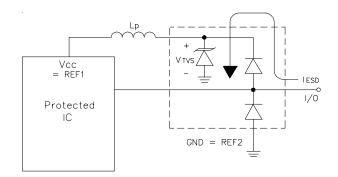

Figure 1 - "Rail-To-Rail" Protection Topology (First Approximation)

Applications Information (continued)

the power supply connection. During an ESD event, the current will be directed through the integrated TVS diode to ground. The total clamping voltage seen by the protected IC due to this path will be:

$$V_{C} = V_{F(RailClamp)} + V_{TVS}$$

This is given in the data sheet as the rated clamping voltage of the device. For an SRDA05-4 the typical clamping voltage is <16V at I =30A. The diodes internal to the RailClamp are Plow capacitance, fast switching devices that are rated to handle high transient currents and maintain excellent forward voltage characteristics.

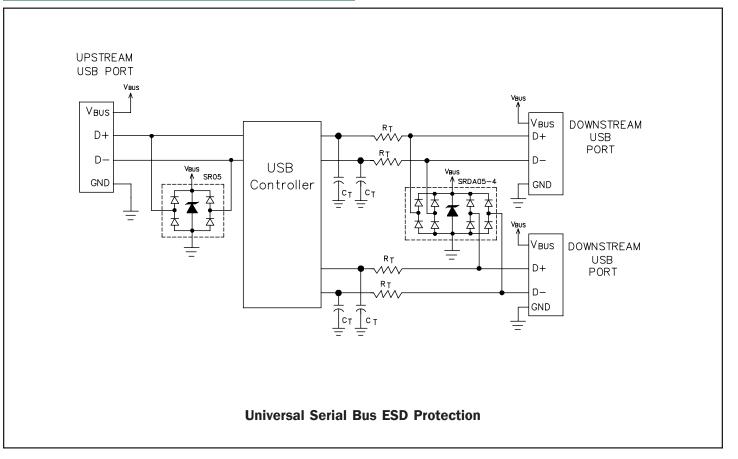

Using the RailClamp does not negate the need for good board layout. All other inductive paths must be considered. The connection between the positive supply and the SRDA and from the ground plane to the SRDA must be kept as short as possible. The path between the SRDA and the protected line must also be minimized. The protected lines should be routed directly to the SRDA. Placement of the SRDA on the PC board is also critical for effective ESD protection. The device should be placed as close as possible to the input connector. The reason for this is twofold. First, inductance resists change in current flow. If a significant inductance exists between the connector and the TVS, the ESD current will be directed elsewhere (lower resistance path) in the system. Second, the effects of radiated emissions and transient coupling can cause upset to other areas of the board even if there is no direct path to the connector. By placing the TVS close to the connector it will divert the ESD current immediately and absorb the ESD energy before it can be coupled into nearby traces.
