POWER UP INITIALIZATION

IS66WV51216EALL and IS66/67WV51216EBLL include an on-chip voltage sensor used to launch the power-up initialization process. When VDD reaches a stable level at or above the VDD (min) the device will require 50µs to complete its self-initialization process. During the initialization period, CS1# should remain HIGH. When initialization is complete, the device is ready for normal operation.

The Data Input Setup and Hold timing are referenced to the rising or falling edge of the signals that terminates the Write.

4. $t_{PWE} > t_{HZWE} + t_{SD}$ when OE# is LOW.

AVOIDABLE TIMING and RECOMMENDATIONS

AVOIDABLE TIMING and RECOMMENDATIONS

Figure 4a : tCSM Violation

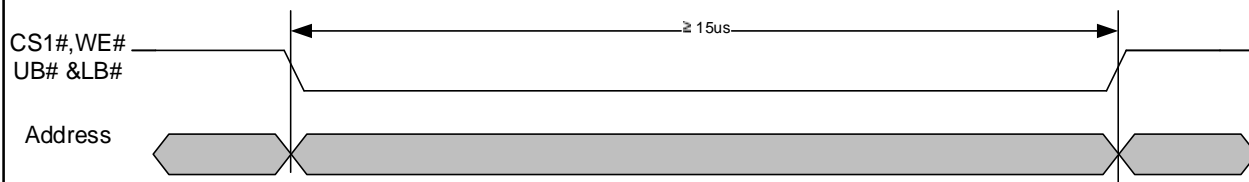

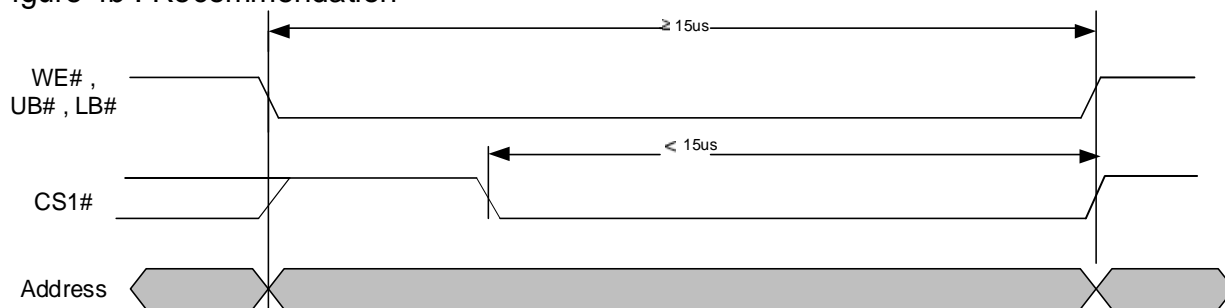

Figure 4b : Recommendation

Notes:

1. PSRAM uses DRAM cell which needs a REFRESH action periodically to retain the information. This REFRESH action is performed only when the device is not selected (Chip Select Pins are Disabled). A hidden REFRESH action has to be executed by the device at least once every $15\mu s$ of tCSM.
2. **Figure 3a** shows a timing example in which consecutive READ cycles for more than $15\mu s$. This timing should be avoided for proper REFRESH operation.
 REFRESH operation can begin only during Chip Select pins are Disabled (CS1# is High and CS2 is Low) for more than $5ns$.
 Example on how to avoid tCSM violation in Figure 3a is shown in Figure 3b.
3. **Figure 4a** shows a timing example in which a single WRITE operation is maintained for a period greater than $15\mu s$. Since a proper REFRESH action cannot be performed during device is selected by Chip Select pins, information stored in the device will not be retained if this timing occurs.
 Figure 4b is a timing example of using CS1# signal toggling for proper the WRITE operation
