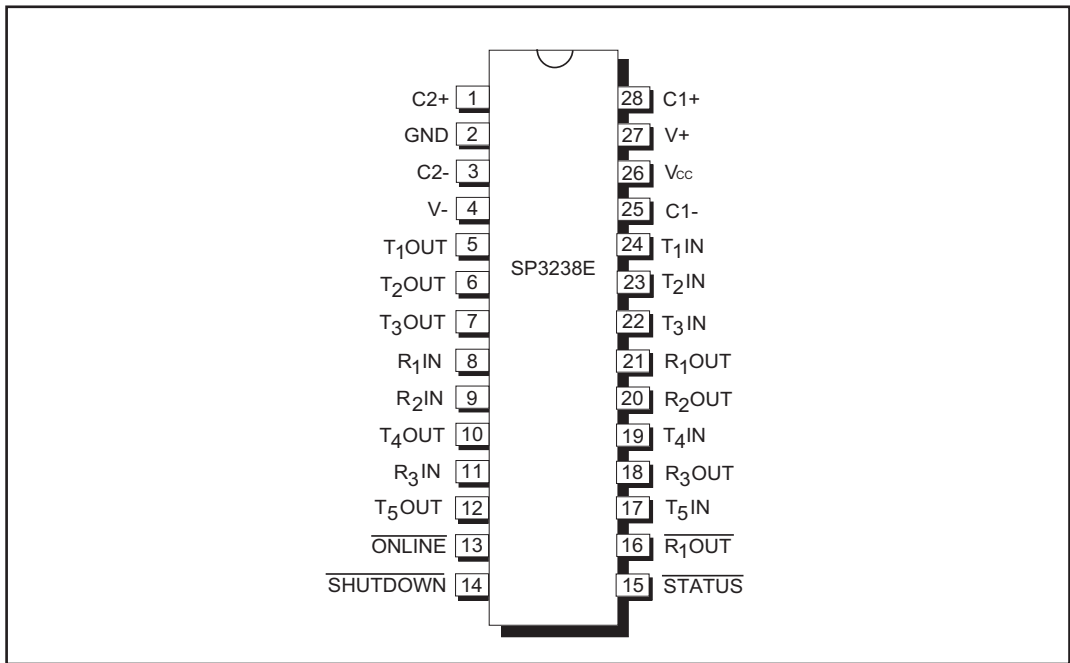

Figure 4. SP3238E Pinout Configuration

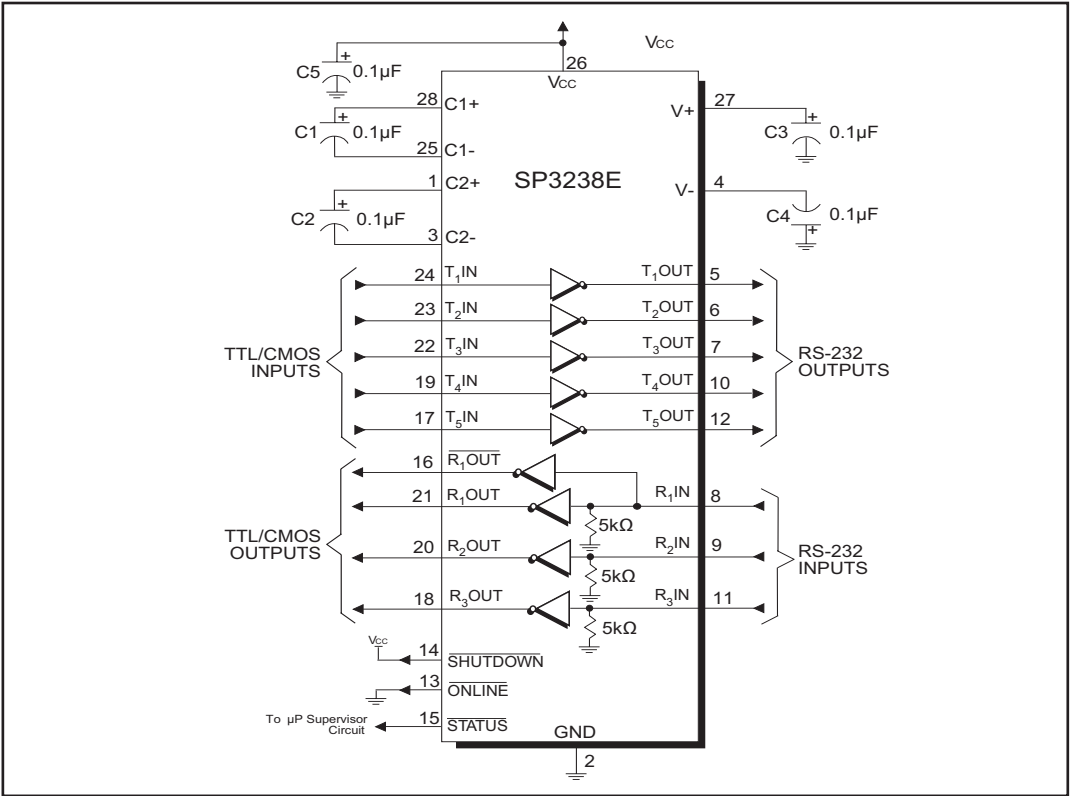

Figure 5. SP3238E Typical Operating Circuit

DESCRIPTION

The SP3238E device meets the EIA/TIA-232 and ITU-T V.28/V.24 communication protocols and can be implemented in battery-powered, portable, or hand-held applications such as notebook or palmtop computers. The SP3238E devices feature Exar's proprietary and patented (U.S.-- 5,306,954) on-board charge pump circuitry that generates $\pm 5.5V$ RS-232 voltage levels from a single $+3.0V$ to $+5.5V$ power supply. The SP3238E devices can guarantee a data rate of 250kbps fully loaded.

The SP3238E is a 5-driver/3-receiver device, ideal for portable or hand-held applications. The SP3238E includes one complementary always-active receiver that can monitor an external device (such as a modem) in shutdown. This aids in protecting the UART or serial controller IC by preventing forward biasing of the protection diodes where V_{CC} may be disconnected.

The SP3238E device is an ideal choice for power sensitive designs. The SP3238E device features **AUTO ON-LINE**® circuitry which reduces the power supply drain to a $1\mu A$ supply current.

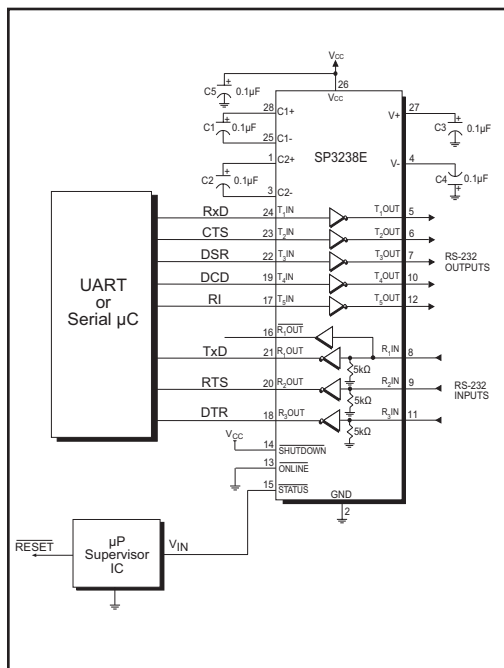

Figure 6. Interface Circuitry Controlled by Microprocessor Supervisory Circuit

In many portable or hand-held applications, an RS-232 cable can be disconnected or a connected peripheral can be turned off. Under these conditions, the internal charge pump and the drivers will be shut down. Otherwise, the system automatically comes online. This feature allows design engineers to address power saving concerns without major design changes.

THEORY OF OPERATION

The SP3238E device is made up of four basic circuit blocks:

1. Drivers
2. Receivers
3. The Exar proprietary charge pump, and
4. **AUTO ON-LINE**® circuitry.

Drivers

The drivers are inverting level transmitters that convert TTL or CMOS logic levels to 5.0V EIA/TIA-232 levels with an inverted sense relative to the input logic levels. Typically, the RS-232 output voltage swing is $\pm 5.4V$ with no load and $\pm 5V$ minimum fully loaded. The driver outputs are protected against infinite short-circuits to ground without degradation in reliability. These drivers comply with the EIA-TIA-232-F and all previous RS-232 versions.

The drivers can guarantee a data rate of 250kbps fully loaded with $3k\Omega$ in parallel with $1000pF$, ensuring compatibility with PC-to-PC communication software. All unused drivers inputs should be connected to GND or V_{CC} .

The slew rate of the driver output is internally limited to a maximum of $30V/\mu s$ in order to meet the EIA standards (EIA RS-232D 2.1.7, Paragraph 5). The transition of the loaded output from HIGH to LOW also meets the monotonicity requirements of the standard.

Figure 7 shows a loopback test circuit used to test the RS-232 drivers. Figure 8 shows the test results of the loopback circuit with all five drivers active at 120kbps with typical RS-232 loads in parallel with $1000pF$ capacitors. Figure 9 shows the test results where one driver was active at 250kbps and all five drivers loaded with an RS-232 receiver in parallel with a $1000pF$ capacitor. A solid RS-232 data transmission rate of 120kbps provides compatibility with many designs in personal computer peripherals and LAN applications.

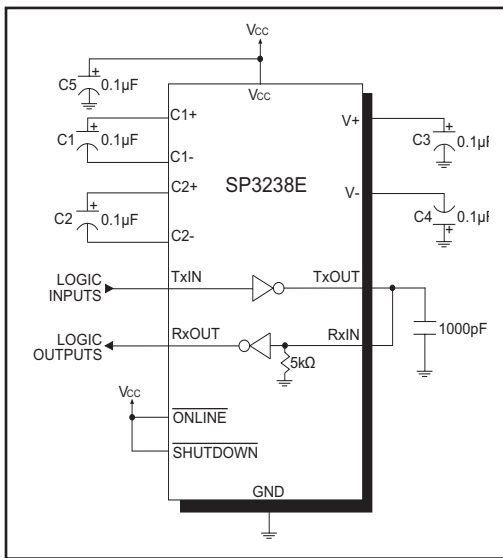

Figure 7. Loopback Test Circuit for RS-232 Driver Data Transmission Rates

Figure 8. Loopback Test results at 120kbps (All Drivers Fully Loaded)

Figure 9. Loopback Test results at 250Kbps (All Drivers Fully Loaded)

Receivers

The receivers convert $\pm 5.0\text{V}$ EIA/TIA-232 levels to TTL or CMOS logic output levels. Receivers are High-Z when the AUTO ON-LINE[®] circuitry is enabled or when in shutdown.

The SP3238E includes an additional non-inverting receiver with an output $R_1\text{OUT}$. $R_1\text{OUT}$ is an extra output that remains active and monitors activity while the other receiver outputs are forced into high impedance. This allows a Ring Indicator (RI) signal from a peripheral to be monitored without forward biasing the TTL/CMOS inputs of the other devices connected to the receiver outputs.

Since receiver input is usually from a transmission line where long cable lengths and system interference can degrade the signal, the inputs have a typical hysteresis margin of 300mV. This ensures that the receiver is virtually immune to noisy transmission lines. Should an input be left unconnected, an internal 5kΩ pulldown resistor to ground will commit the output of the receiver to a HIGH state.

Charge Pump

The charge pump is an Exar-patented design (U.S. 5,306,954) and uses a unique approach compared to older less-efficient designs. The charge pump still requires four external capacitors, but uses a four-phase voltage shifting technique to attain symmetrical 5.5V power supplies. The internal power supply consists of a regulated dual charge pump that provides output voltages 5.5V regardless of the input voltage (V_{CC}) over the +3.0V to +5.5V range. This is important to maintain compliant RS-232 levels regardless of power supply fluctuations.

The charge pump operates in a discontinuous mode using an internal oscillator. If the output voltages are less than a magnitude of 5.5V, the charge pump is enabled. If the output voltages exceed a magnitude of 5.5V, the charge pump is disabled. This oscillator controls the four phases of the voltage shifting. A description of each phase follows.

Phase 1

— V_{SS} charge storage — During this phase of the clock cycle, the positive side of capacitors C_1 and C_2 are initially charged to V_{CC} . C_1^+ is then switched to GND and the charge in C_1^- is transferred to C_2^- . Since C_2^+ is connected to V_{CC} , the voltage potential across capacitor C_2 is now 2 times V_{CC} .

Phase 2

— V_{SS} transfer — Phase two of the clock cycle connects the negative terminal of C_2 to the V_{SS} storage capacitor and the positive terminal of C_2 to GND. This transfers a negative generated voltage to C_3 . This generated voltage is regulated to a minimum voltage of -5.5V. Simultaneous with the transfer of the voltage to C_3 , the positive side of capacitor C_1 is switched to V_{CC} and the negative side is connected to GND.

Phase 3

— V_{DD} charge storage — The third phase of the clock is identical to the first phase — the charge transferred in C_1 produces $-V_{CC}$ in the negative terminal of C_1 , which is applied to the negative side of capacitor C_2 . Since C_2^+ is at V_{CC} , the voltage potential across C_2 is 2 times V_{CC} .

Phase 4

— V_{DD} transfer — The fourth phase of the clock connects the negative terminal of C_2 to GND, and transfers this positive generated voltage across C_2 to C_4 , the V_{DD} storage capacitor. This voltage is regulated to +5.5V. At this voltage, the internal oscillator is disabled. Simultaneous with the transfer of the voltage to C_4 , the positive side of capacitor C_1 is switched to V_{CC} and the negative side is connected to GND, allowing the charge pump cycle to begin again. The charge pump cycle will continue as long as the operational conditions for the internal oscillator are present.

Since both V^+ and V^- are separately generated from V_{CC} , in a no-load condition V^+ and V^- will be symmetrical. Older charge pump approaches that generate V^- from V^+ will show a decrease in the magnitude of V^- compared to V^+ due to the inherent inefficiencies in the design.

The clock rate for the charge pump typically operates at 500kHz. The external capacitors can be as low as 0.1 μ F with a 16V breakdown voltage rating.

Figure 14. Charge Pump — Phase 4

The SP3238E device has a patent pending **AUTO ON-LINE**[®] circuitry on board that saves power in applications such as laptop computers, palmtop (PDA) computers and other portable systems.

The SP3238E device incorporates an **AUTO ON-LINE**[®] circuit that automatically enables itself when the external transmitters are enabled and the cable is connected. Conversely, the **AUTO ON-LINE**[®] circuit also disables most of the internal circuitry when the device is not being used and goes into a standby mode where the device typically draws 1 μ A. This function is externally controlled by the $\overline{\text{ONLINE}}$ pin. When this pin is tied to a logic LOW, the **AUTO ON-LINE**[®] function is active. Once active, the device is enabled until there is no activity on the receiver inputs. The receiver input typically sees at least $\pm 3\text{V}$, which are generated from the transmitters at the other end of the cable with a $\pm 5\text{V}$ minimum. When the external transmitters are disabled or the cable is disconnected, the receiver inputs will be pulled down by their internal 5k Ω resistors to ground. When this occurs over a period of time, the internal transmitters will be disabled and the device goes into a shutdown or standby mode. When $\overline{\text{ONLINE}}$ is HIGH, the **AUTO ON-LINE**[®] mode is disabled.

The **AUTO ON-LINE**[®] circuit has two stages:

- 1) Inactive Detection
- 2) Accumulated Delay

The first stage, shown in Figure 17, detects an inactive input. A logic HIGH is asserted on $R_{x\text{INACT}}$ if the cable is disconnected or the external transmitters are disabled. Otherwise, $R_{x\text{INACT}}$ will be at a logic LOW. This circuit is duplicated for each of the other receivers.

The second stage of the **AUTO ON-LINE**[®] circuitry, shown in Figure 18, processes all the receiver's $R_{x\text{INACT}}$ signals with an accumulated delay that disables the device to a 1 μ A supply current. The $\overline{\text{STATUS}}$ pin goes to a logic LOW when the cable is disconnected, the external transmitters are disabled, or the **SHUTDOWN** pin is invoked. The typical accumulated delay is around 20 μ s. When the SP3238E drivers or internal charge pump are disabled, the supply current is reduced to 1 μ A. This can commonly occur in handheld or portable applications where

the RS-232 cable is disconnected or the RS-232 drivers of the connected peripheral are turned off.

The **AUTO ON-LINE**[®] mode can be disabled by the **SHUTDOWN** pin. If this pin is a logic LOW, the **AUTO ON-LINE**[®] function will not operate regardless of the logic state of the $\overline{\text{ONLINE}}$ pin. Table 3 summarizes the logic of the **AUTO ON-LINE**[®] operating modes.

The $\overline{\text{STATUS}}$ pin outputs a logic LOW signal if the device is shutdown. This pin goes to a logic HIGH when the external transmitters are enabled and the cable is connected.

When the SP3238E device is shutdown, the charge pumps are turned off. V+ charge pump output decays to V_{cc} , the V- output decays to GND. The decay time will depend on the size of capacitors used for the charge pump. Once in shutdown, the time required to exit the shutdown state and have valid V+ and V- levels is typically 200ms.

For easy programming, the $\overline{\text{STATUS}}$ can be used to indicate DTR or a Ring Indicator signal. Tying $\overline{\text{ONLINE}}$ and **SHUTDOWN** together will bypass the **AUTO ON-LINE**[®] circuitry so this connection acts like a shutdown input pin

ESD TOLERANCE

The SP3238E device incorporates ruggedized ESD cells on all driver output and receiver input pins. The ESD structure is improved over our previous family for more rugged applications and environments sensitive to electro-static discharges and associated transients. The improved ESD tolerance is at least $\pm 15\text{kV}$ without damage nor latch-up.

There are different methods of ESD testing applied:

- a) MIL-STD-883, Method 3015.7
- b) IEC61000-4-2 Air-Discharge
- c) IEC61000-4-2 Direct Contact

The Human Body Model has been the generally accepted ESD testing method for semi-conductors. This method is also specified in MIL-STD-883, Method 3015.7 for ESD testing. The premise of this ESD test is to simulate the human body's potential to store electro-static energy and discharge it to an integrated circuit. The simulation is performed by using a test model as shown in Figure 19. This method will test the IC's capability to withstand an ESD transient during normal handling such as in manufacturing areas where the IC's tend to be handled frequently.

The IEC-61000-4-2, formerly IEC801-2, is generally used for testing ESD on equipment and systems. For system manufacturers, they must guarantee a certain amount of ESD protection since the system itself is exposed to the outside environment and human presence. The premise with IEC61000-4-2 is that the system is required to withstand an amount of static electricity when ESD is applied to points and surfaces of the equipment that are accessible to personnel during normal usage. The transceiver IC receives

most of the ESD current when the ESD source is applied to the connector pins. The test circuit for IEC61000-4-2 is shown on Figure 20. There are two methods within IEC61000-4-2, the Air Discharge method and the Contact Discharge method.

With the Air Discharge Method, an ESD voltage is applied to the equipment under test (EUT) through air. This simulates an electrically charged person ready to connect a cable onto the rear of the system only to find an unpleasant zap just before the person touches the back panel. The high energy potential on the person discharges through an arcing path to the rear panel of the system before he or she even touches the system. This energy, whether discharged directly or through air, is predominantly a function of the discharge current rather than the discharge voltage. Variables with an air discharge such as approach speed of the object carrying the ESD potential to the system and humidity will tend to change the discharge current. For example, the rise time of the discharge current varies with the approach speed.

The Contact Discharge Method applies the ESD current directly to the EUT. This method was devised to reduce the unpredictability of the ESD arc. The discharge current rise time is constant since the energy is directly transferred without the air-gap arc. In situations such as hand held systems, the ESD charge can be directly discharged to the equipment from a person already holding the equipment. The current is transferred on to the keypad or the serial port of the equipment directly and then travels through the PCB and finally to the IC.

Figure 19. ESD Test Circuit for Human Body Model

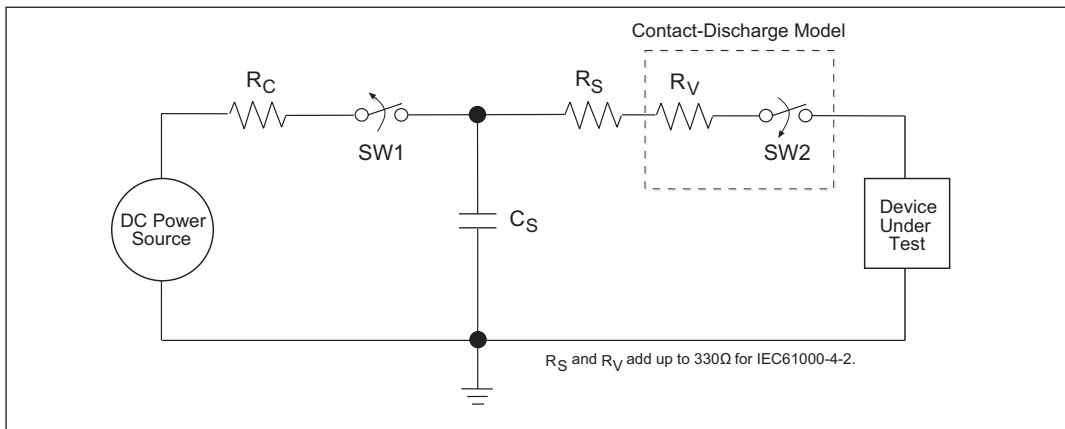

Figure 20. ESD Test Circuit for IEC61000-4-2

The circuit models in Figures 19 and 20 represent the typical ESD testing circuit used for all three methods. The C_s is initially charged with the DC power supply when the first switch (SW1) is on. Now that the capacitor is charged, the second switch (SW2) is on while SW1 switches off. The voltage stored in the capacitor is then applied through R_s , the current limiting resistor, onto the device under test (DUT). In ESD tests, the SW2 switch is pulsed so that the device under test receives a duration of voltage.

For the Human Body Model, the current limiting resistor (R_s) and the source capacitor (C_s) are 1.5kΩ and 100pF, respectively. For IEC-61000-4-2, the current limiting resistor (R_s) and the source capacitor (C_s) are 330Ω and 150pF, respectively.

The higher C_s value and lower R_s value in the IEC61000-4-2 model are more stringent than the Human Body Model. The larger storage capacitor injects a higher voltage to the test point when SW2 is switched on. The lower current limiting resistor increases the current charge onto the test point.
