### NOTES

<sup>1</sup>Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.

<sup>2</sup>Overtages at IN, S or D will be clamped by internal diodes. Current should be limited to the maximum ratings given.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADG752 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## GENERAL DESCRIPTION

The ADG752 is an SPDT switch constructed using switches in a T configuration to obtain high “OFF” isolation while maintaining good frequency response in the “ON” condition.

Figure 8 shows the T-switch configuration. While the switch is in the OFF state, the shunt switch is closed and the two series switches are open. The closed shunt switch provides a signal path to ground for any of the unwanted signals that find their way through the off capacitances of the series’ MOS devices. This results in more improved isolation between the input and output than with an ordinary series switch. When the switch is in the ON condition, the shunt switch is open and the signal path is through the two series switches which are now closed.

## LAYOUT CONSIDERATIONS

Where accurate high frequency operation is important, careful consideration should be given to the printed circuit board layout and to grounding. Wire wrap boards, prototype boards and sockets are not recommended because of their high parasitic inductance and capacitance. The part should be soldered directly to a printed circuit board. A ground plane should cover all unused areas of the component side of the board to provide a low impedance path to ground. Removing the ground planes from the area around the part reduces stray capacitance.

Good decoupling is important in achieving optimum performance.  $V_{DD}$  should be decoupled with a 0.1  $\mu\text{F}$  surface mount capacitor to ground mounted as close as possible to the device itself.
