

## Typical Applications Circuit

Typical Application of AP3776 with AP4341 ( $V_{OUT}=5V/1A$  or  $2A$ )

Typical Application of AP3776 with APR343 ( $V_{OUT}=5V/2A$  or  $2.4A$ )

## Typical Applications Circuit (Cont.)

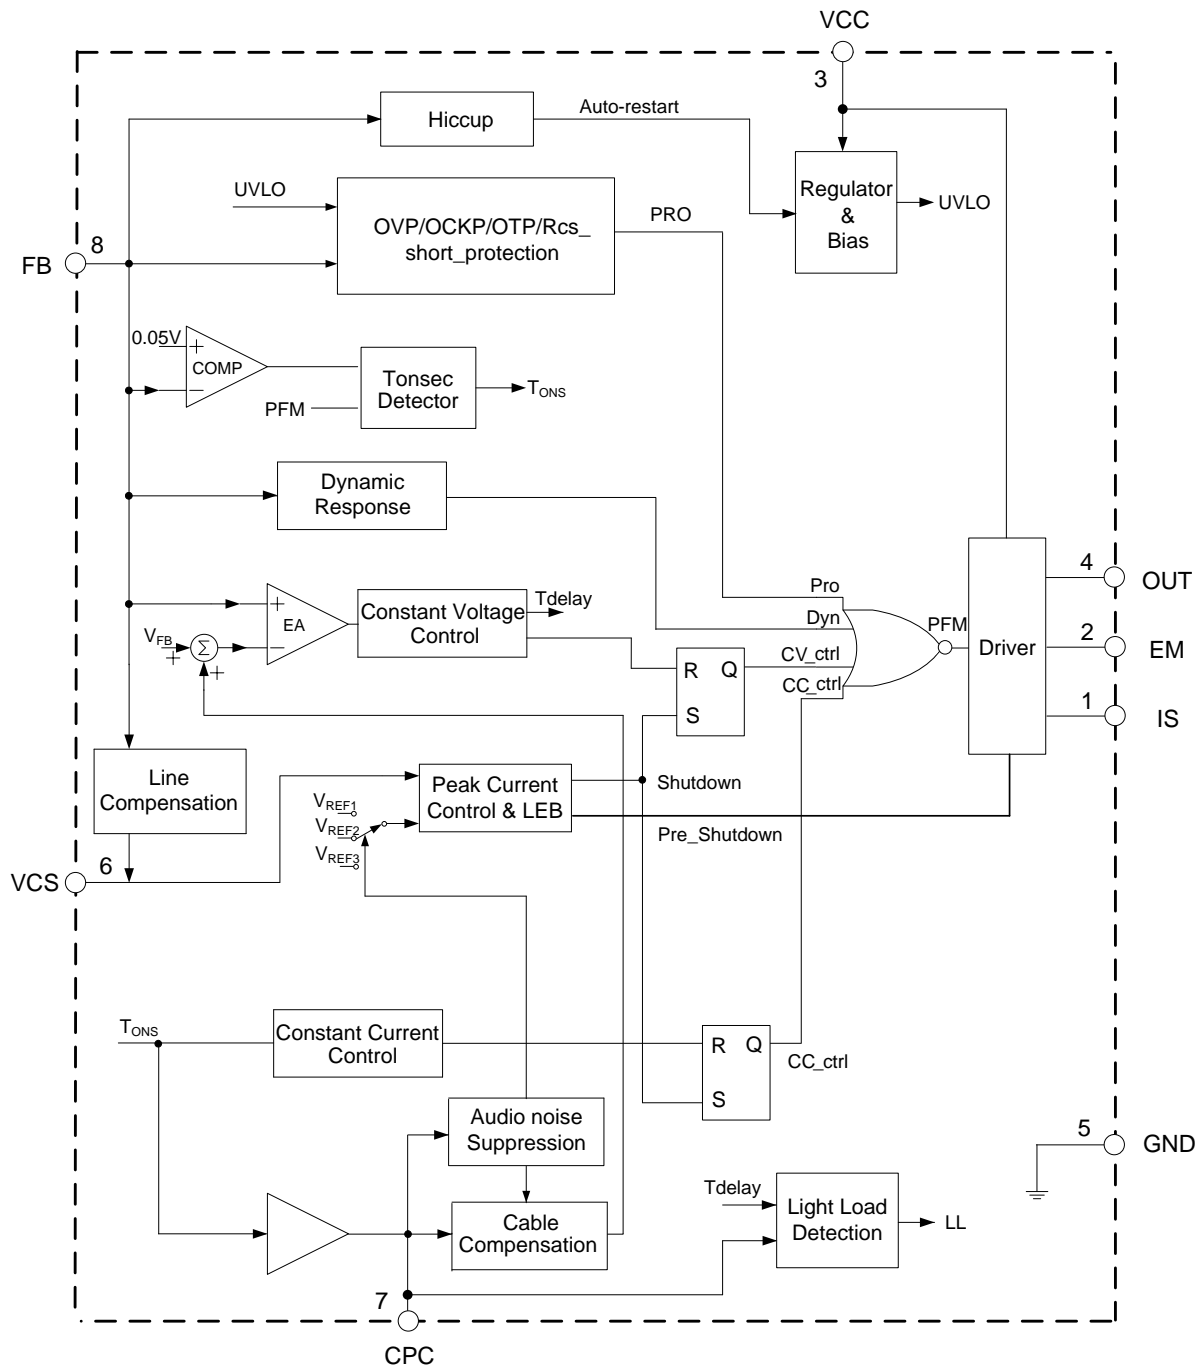

Typical Application of AP3776 with APR3415 ( $V_{OUT}=5V/2A$  or  $2.4A$ )

## Pin Descriptions

Pin Number	Pin Name	Function
1	IS	Primary current sensing
2	EM	Connected to the source of external power MOSFET
3	VCC	Power supply
4	OUT	Driving the gate of external power MOSFET
5	GND	Ground
6	VCS	Current sensing voltage
7	CPC	Connecting a capacitor for output cable compensation
8	FB	Voltage feedback

## Functional Block Diagram

## Absolute Maximum Ratings (Note 4)

Symbol	Parameter		Rating	Unit
$V_{CC}$	Voltage at VCC to GND		-0.3 to 28	V
–	Voltage at OUT, EM to GND		-0.3 to 23	V
–	Voltage at IS, VCS, CPC to GND		-0.3 to 7	V
–	FB Input		-40 to 10	V
–	Output Current at OUT		Internally limited	A
$T_J$	Operating Junction Temperature		+150	°C
$T_{STG}$	Storage Temperature		-65 to +150	°C
$T_{LEAD}$	Lead Temperature (Soldering, 10 Sec)		+300	°C
$\theta_{JA}$	Thermal Resistance Junction-to-Ambient		+190	°C/W
ESD	Electrostatic Discharge Capability	Human Body Model	6000	V
		Charged Device Model	2500	V
		Machine Model	200	V

Note 4: Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "Recommended Operating Conditions" is not implied. Exposure to "Absolute Maximum Ratings" for extended periods may affect device reliability.

## Function Description

### Operation Description

#### 1. Start-up Circuit

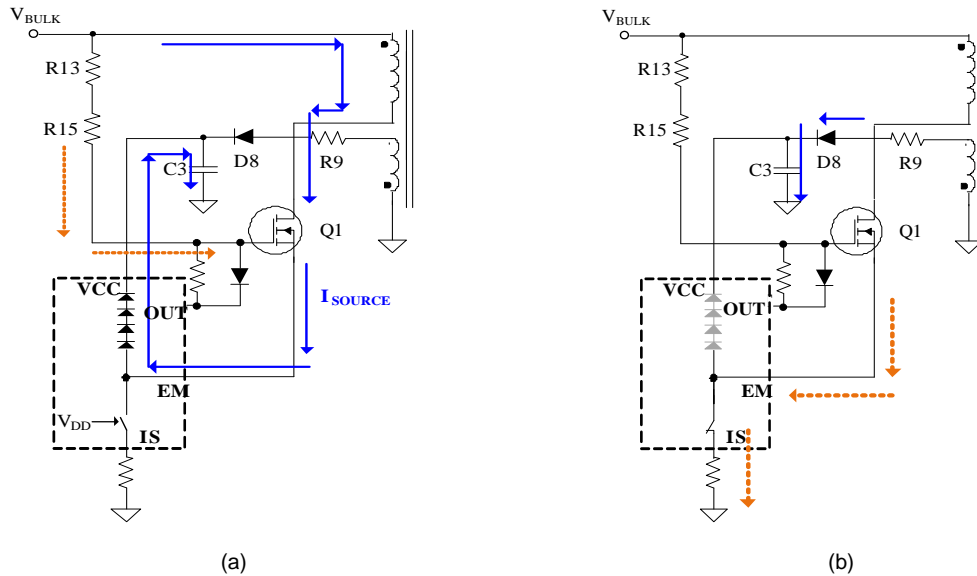

Figure 1. The AP3776 Start-up Circuit

Figure1 (a) shows the Startup Phase

- Before  $V_{CC}$  reaches  $V_{TH}(ST)$ ,  $V_{DD}$  is zero and  $EM$  to  $IS$  pin is open.
- $C_3$  is charged by  $I_{SOURCE}$ .
- The resistance of  $R_{13}$  and  $R_{15}$  should be big enough to reduce the power dissipation.

Figure1 (b) shows the Normal Operation Phase

- When  $V_{CC}$  reaches  $V_{TH}(ST)$ ,  $V_{DD}$  is high and  $EM$  to  $IS$  pin is short.
- The voltage of  $EM$  pin is lower than 1V so that the four diodes in chip are open.
- $C_3$  is supplied by Aux. winding of transformer.

#### 2. Operation Mode

The typical application circuit of AP3776 is a conventional Flyback converter with a 3-winding transformer---primary winding ( $N_P$ ), secondary winding ( $N_S$ ) and auxiliary winding ( $N_{AUX}$ ), as shown in typical application of AP3776 with AP4341. The auxiliary winding is used for providing  $V_{CC}$  supply voltage for IC and sensing the output voltage feedback signal to  $FB$  pin.

Figure 2 shows the typical waveforms which demonstrate the basic operating principle of AP3776 application. And the parameters are defined as following.

- $I_P$ ---The primary side current
- $I_S$ ---The secondary side current
- $I_{PK}$ ---Peak value of primary side current
- $I_{PKS}$ ---Peak value of secondary side current
- $V_{SEC}$ ---The transient voltage at secondary winding
- $V_S$ ---The stable voltage at secondary winding when rectification diode is in conducting status, which equals the sum of output voltage  $V_{OUT}$  and the forward voltage drop of diode
- $V_{AUX}$ ---The transient voltage at auxiliary winding
- $V_A$ --- The stable voltage at auxiliary winding when rectification diode is in conducting status, which equals the sum of voltage  $V_{CC}$  and the forward voltage drop of auxiliary diode
- $t_{SW}$  ---The period of switching frequency
- $t_{ONP}$  ---The conduction time when primary side switch is "ON"
- $t_{ONS}$  ---The conduction time when secondary side diode is "ON"
- $t_{OFF}$  ---The dead time when neither primary side switch nor secondary side diode is "ON"
- $t_{OFFS}$  --- The time when secondary side diode is "OFF"

## Function Description (Cont.)

Figure 2. The Operation Waveform of Flyback PSR System

For primary-side regulation, the primary current  $i_p(t)$  is sensed by a current sense resistor  $R_{CS}$  (R5,R6 as shown in Typical Application of AP3776). The current rises up linearly at a rate of:

$$\frac{di_p(t)}{dt} = \frac{V_{in}(t)}{L_M} \quad (1)$$

As illustrated in Figure 2, when the current  $i_p(t)$  rises up to  $I_{PK}$ , the switch Q1 turns off. The constant peak current is given by:

$$I_{PK} = \frac{V_{CS}}{R_{CS}} \quad (2)$$

The energy stored in the magnetizing inductance  $L_M$  each cycle is therefore:

$$E_g = \frac{1}{2} \times L_M \cdot I_{PK}^2 \quad (3)$$

So the power transferring from the input to the output is given by:

$$P = \frac{1}{2} \times L_M \times I_{PK}^2 \times f_{SW} \quad (4)$$

Where, the  $f_{SW}$  is the switching frequency. When the peak current  $I_{PK}$  is constant, the output power depends on the switching frequency  $f_{SW}$ .

The maximum frequency for AP3776 system is about 84kHz.

### Constant Voltage Operation

As to constant-voltage (CV) operation mode, the AP3776 detects the auxiliary winding voltage at FB pin to regulate the output voltage. The auxiliary winding voltage is coupled with secondary side winding voltage, so the auxiliary winding voltage at secondary rectification diode D1 conduction time is:

$$V_{AUX} = \frac{N_{AUX}}{N_S} \times (V_{OUT} + V_d) \quad (5)$$

Where the  $V_d$  is the diode forward voltage drop.

## Function Description (Cont.)

Figure 3. Auxiliary Voltage Waveform

The voltage detection point is at 2/3 of the D1 on-time. The voltage detection point is changed with the different primary peak current. The CV loop control function of AP3776 then generates a D1 off-time to regulate the output voltage.

### Constant Current Operation

The AP3776 can work in constant-current (CC) mode. Figure 2 shows the secondary current waveforms.

In CC operation mode, the CC control loop of AP3776 will keep a fixed proportion between D1 on-time  $T_{ons}$  and D1 off-time  $T_{offs}$ . The fixed proportion is

$$\frac{T_{ons}}{T_{offs}} = \frac{4}{4} \quad (6)$$

The relationship between the output current and secondary peak current  $I_{PKS}$  is given by:

$$I_{OUT} = \frac{1}{2} \times I_{PKS} \times \frac{T_{ons}}{T_{ons} + T_{offs}} \quad (7)$$

As to tight coupled primary and secondary winding, the secondary peak current is

$$I_{PKS} = \frac{N_p}{N_s} \times I_{PK} \quad (8)$$

Thus the output constant-current is given by:

$$I_{OUT} = \frac{1}{2} \times \frac{N_p}{N_s} \times I_{PK} \times \frac{T_{ons}}{T_{ons} + T_{offs}} = \frac{2}{8} \times \frac{N_p}{N_s} \times I_{PK} \quad (9)$$

Therefore, AP3776 can realize CC mode operation by constant primary peak current and fixed diode conduction duty cycle.

### Multiple Segment Constant Peak Current

As to the original PFM PSR system, the switching frequency decreases with output current decreasing, which will encounter audible noise issue since switching frequency decrease to audio frequency range, about less than 20kHz.

In order to avoid audible noise issue, AP3776 uses 3-segment constant primary peak current control method. At constant voltage mode, the current sense threshold voltage is multiple segments with different loading, as shown in Figure 4, which are  $V_{CS\_H}$  for high load,  $V_{CS\_M}$  for medium load and  $V_{CS\_L}$  for light load. At constant current mode, the peak current is still  $V_{CS\_H}$ . As to no load and ultra light load condition (LL mode), the current reference is also  $V_{CS\_L}$ . But the LL mode operating is different, which will be described in next section.

It can be seen from the following Figure 4 that with multiple segment peak current control, AP3776 power system can keep switching frequency above 24kHz from light load to heavy load and guarantee the audible noise free performance.

## Function Description (Cont.)

Figure 4. Multiple Segment Peak Current at CV Mode

### 3. The LL Mode Operating (Typical Application with APR343)

At no load and light load, the AP3776 works in Low Light mode (LL mode) and the output voltage is detected by APR343. In order to achieve ultra low standby power in LL mode, the static current ( $I_{CC\_NL}$ ) of the AP3776 is reduced from 280μA to 100μA.

- The conditions of exiting LL mode--- $V_{CPC} > 65mV$  or  $t_{OFF} < t_{DELAY} + 30\mu s$
- The conditions of entering LL mode--- $V_{CPC} < 33mV$  and  $t_{OFF} \geq t_{DELAY} + 30\mu s$

In LL mode, when the APR343 detects the output voltage is lower than its trigger voltage, the APR343 VDET pin emits a periodical pulse current. This pulse current will generate a pulse voltage on feedback winding through the transformer coupling. When the AP3776 detects this  $V_{PULSE}$  (>100mV is valid), primary switch immediately turns on to provide one energy pulse to supply output terminal and primary  $V_{CC}$ . To achieve low standby power, the lower switching frequency is necessary. But if the off time is too long, the  $V_{CC}$  voltage will reduce to very low level. To avoid  $V_{CC}$  being lower than  $V_{OPR(Min)}$ , a minimum switching frequency is specified by the APR343 ( $t_{DIS}$ ). If  $V_{OUT}$  does not fall below trigger voltage during  $t_{DIS}$ , APR343 VDET pin will emit the periodical pulse current and let the primary switch turn on.

### 4. Leading Edge Blanking

When the power switch is turned on, a turn-on spike will occur on the sense-resistor. To avoid false-termination of the switching pulse, a 500ns leading-edge blanking (from power MOSFET on) is built in. During this blanking period, the current sense comparator is disabled and the gate driver can't be switched off.

### 5. Adjustable Line Compensation

Since there is a constant delay time from the CS pin voltage reaching the given  $V_{CS}$  reference to the power MOSFET turning off, the real primary peak current value always has a gap with the ideal value. The gap value changes with different input line voltage, which is caused by different current rising slope, results in different system constant current value.

In order to eliminate the constant current deviation due to line voltage, the adjustable line compensation is introduced to AP3776 design. By sensing the negative voltage of FB pin which is linear to the line voltage, a current ( $I_{LINE}$ ) proportional to line voltage flows out from the CS pin to the resistor  $R_{LINE}$ , and create an adjustable compensation voltage to clear up the primary current gap, so that the excellent line regulation of output current will be achieved.

$$V_{CS\_LINE} = R_{LINE} \cdot 0.4 \cdot \frac{1}{700k} \cdot \frac{R_{FB2}}{R_{FB1} + R_{FB2}} \cdot \frac{N_{aux}}{N_p} \cdot V_{indc}$$

## Function Description (Cont.)

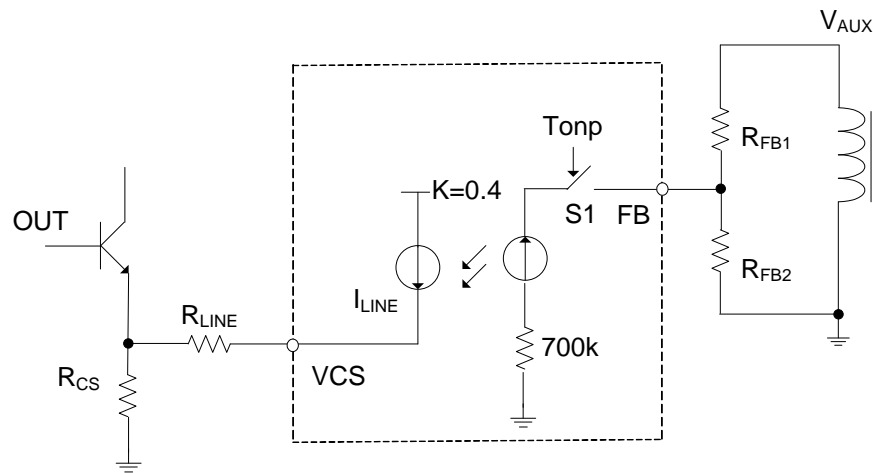

Figure 5. Adjustable Line Compensation Circuit

### 6. Fixed Cable Compensation

As we know, CPC voltage reflects the power system loading percentage. By introducing a rising voltage, which is linear to CPC voltage, to the FB reference voltage, AP3776 can realize the fixed cable compensation to match the voltage drop at output cable. The cable compensation is 7% (typ).

### Protection

#### 1. FB Over Voltage Protection (OVP)

When the voltage of FB pin exceeds  $V_{FB(OVP)}$  at  $T_{ons}$  period, AP3776 immediately shuts down for  $t_{OFF(MAX)}$  and then detects the FB voltage again to see if  $V_{FB(OVP)}$  condition is removed. The  $V_{CC}$  voltage will drop during the  $t_{OFF(MAX)}$ . When  $V_{CC}$  is still higher than  $V_{OPR(Min)}$  after  $t_{OFF(MAX)}$ , and  $V_{FB(OVP)}$  condition is removed, the IC will enter normal operating mode; but if  $V_{FB(OVP)}$  condition is not removed, AP3776 will remain shut down and wait for another  $t_{OFF(MAX)}$ . When  $V_{CC}$  drops to  $V_{OPR(Min)}$  during the  $t_{OFF(MAX)}$ , AP3776 will enter the restart mode, and  $V_{CC}$  voltage changes between  $V_{TH(ST)}$  and  $V_{OPR(Min)}$  until  $V_{FB(OVP)}$  condition is removed.

#### 2. Open Circuit Protection (OCKP)

If the down resistance of FB pin short or up resistance open, there will be no voltage on FB pin, so the sample signal can't be monitored, and the OCKP protection will be triggered. The protection operating process is the same as over voltage protection process.

#### 3. Short Circuit Protection (SCP)

Short Circuit Protection (SCP) detection principle is similar to the normal output voltage feedback detection by sensing FB pin voltage. When the detected FB pin voltage is below  $V_{FB(SCP)}$  for a duration of about  $t_{OFF(MAX)}$ , the SCP is triggered. Then the AP3776 enters hiccup mode that the IC immediately shuts down and then restarts, so that the  $V_{CC}$  voltage changes between  $V_{TH(ST)}$  and  $V_{OPR(Min)}$  until  $V_{FB(SCP)}$  condition is removed.

As to the normal system startup, the time duration of FB pin voltage below  $V_{FB(SCP)}$  should be less than  $t_{OFF(MAX)}$  to avoid entering SCP mode. But for the output short condition or the output voltage below a certain level, the SCP mode should happen.

Figure 6 shows the AP3776 normal start-up waveform. If the voltage of FB pin reaches above  $V_{FB(SCP)}$  during  $t_{OFF(MAX)}$  after  $V_{CC}$  gets to the  $V_{TH(ST)}$ , the IC doesn't enter the SCP mode. Figure 7 shows that  $V_{OUT}$  is short and the voltage of FB pin is lower than  $V_{FB(SCP)}$  during  $t_{OFF(MAX)}$ , then the AP3776 triggers the SCP and enters the hiccup mode.

## Function Description (Cont.)

Figure 6. Normal Start-up

Figure 7. Short Circuit Protection (SCP) and Hiccup Mode

### 4. $R_{CS}$ Short Protection

When the primary side current sense resistance is shorted, the primary side current rapidly increases, and the transformer saturates, which leads to some components' damage. The AP3776 draws in the  $R_{CS}$  short protection to avoid the damage. If the voltage of CS pin is smaller than 0.15V at the primary side maximum on time  $t_{onp}(MAX)$ , the  $R_{CS}$  short protection is triggered, and the AP3776 immediately shuts down, and then restarts.

### 5. Over Temperature Protection (OTP)

When the IC junction temperature exceeds the thermal shutdown temperature threshold of +130°C, the device shuts down immediately. Retry is allowed if junction temperature reduces by hysteresis temperature value.

**LIFE SUPPORT**

Diodes Incorporated products are specifically not authorized for use as critical components in life support devices or systems without the express written approval of the Chief Executive Officer of Diodes Incorporated. As used herein:

A. Life support devices or systems are devices or systems which:

1. are intended to implant into the body, or
2. support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in significant injury to the user.

B. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or to affect its safety or effectiveness.

Customers represent that they have all necessary expertise in the safety and regulatory ramifications of their life support devices or systems, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of Diodes Incorporated products in such safety-critical, life support devices or systems, notwithstanding any devices- or systems-related information or support that may be provided by Diodes Incorporated. Further, Customers must fully indemnify Diodes Incorporated and its representatives against any damages arising out of the use of Diodes Incorporated products in such safety-critical, life support devices or systems.
