SHDN Pin Low	Shutdown Mode			0.4	V

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

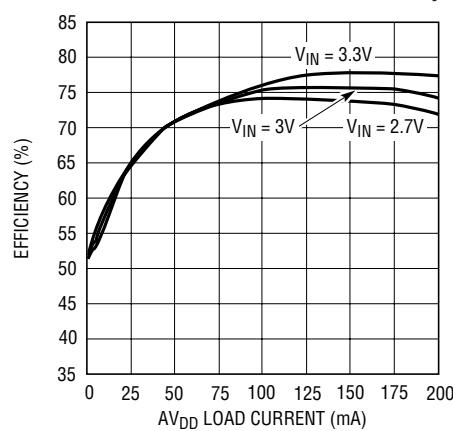

Note 2: The LT1947 is guaranteed to meet performance specifications from 0°C to 70°C . Specifications over the -40°C to 85°C operating

temperature range are assured by design, characterization and correlation with statistical process controls.

Note 3: Switch current limit guaranteed by design and/or correlation to static tests.

PIN FUNCTIONS

FB1 (Pin 1): Feedback Pin for First Switcher. Connect resistor divider tap here. Set $A_{V_{DD}}$ according to:
 $A_{V_{DD}} = 1.26V(1 + R1/R2)$.

FB2 (Pin 2): Feedback Pin for Second Switcher. Connect resistor divider 2 here and set V_{ON} using:
 $V_{ON} = 1.26V(1 + R3/R4) - 160mV$.

C_T(Pin 3): Timing Capacitor Pin. Connect a 10nF capacitor from C_T to ground to program a 2.3ms delay from FB1 reaching 1.26V to V_{ON} turning on.

SW1 (Pin 4): A_{V_{DD}} Switch Node. Connect L1 and D1 here (see Figure 1). Minimize trace area at this pin to keep EMI down.

GND (Pin 5): Ground. Connect directly to local ground plane.

V_{IN} (Pin 6): Input Supply Pin. Must be bypassed with a ceramic capacitor close to the pin.

SW2 (Pin 7): V_{O2} Switch Node. Connect L2 and D2 here. Minimize trace area at this pin to keep EMI down.

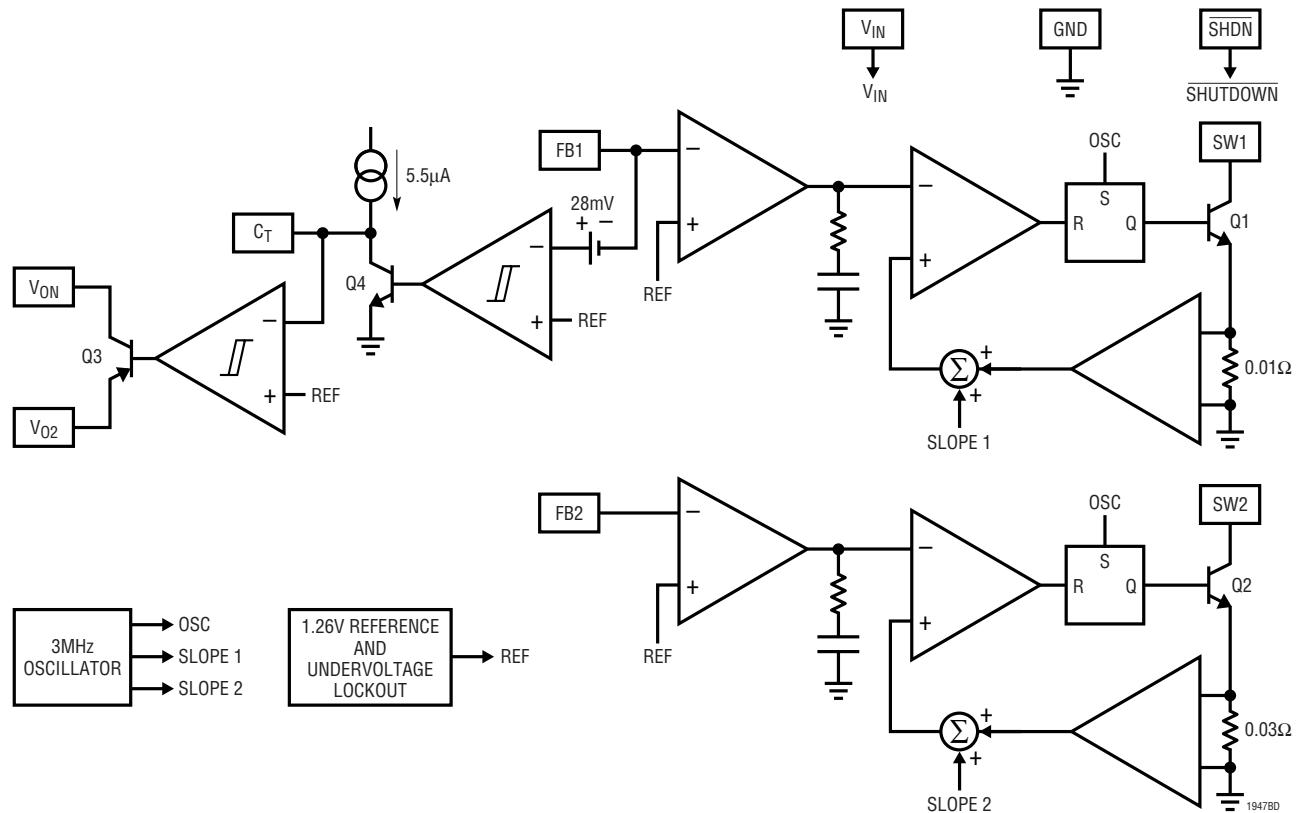

SHDN (Pin 8): Pull this pin low for shutdown mode. For normal operation, tie to a voltage between 2.4V and 8V.

V_{O2} (Pin 9): SW2 Output. This node is also internally connected to the emitter of Q3 (see Block Diagram), the high side switch between V_{O2} and V_{ON}.

V_{ON} (Pin 10): This is the delayed output for second Switcher. V_{ON} reaches its programmed voltage after the internal timer times out.

Exposed Pad (Pin 11): Ground (MSE package only). The exposed pad must be soldered to the PCB and electrically connected to ground.

BLOCK DIAGRAM

OPERATION

To best understand operation of the LT1947, please refer to the LT1947 Block Diagram. The device contains two switching regulators, a timer and a high side switch. Three outputs can be generated: an adjustable AV_{DD} output, a charge-pumped inversion of the AV_{DD} output called V_{OFF} , and a time delayed adjustable output called V_{ON} . Q3 keeps V_{ON} off for an externally set time interval, set by a capacitor connected to the C_T pin.

The switching frequency of both switchers is 3MHz, set internally. The switchers are current mode and are internally compensated. The main AV_{DD} switcher is current limited at 1.1A, while the second V_{ON} switcher is limited to 350mA. They share the same 1.26V reference voltage. When the input voltage is below approximately 2.7V, an undervoltage lockout circuit disables switching.

When AV_{DD} is less than its final voltage, Q4 is turned on, holding the C_T pin at ground. When AV_{DD} reaches final value, Q4 lets go of the C_T pin, allowing the $5.5\mu A$ current source to charge the external capacitor, C_T . When the voltage on the C_T pin reaches 1.28V, Q3 turns on, connecting V_{O2} to V_{ON} . Capacitor value can be calculated using the following formula:

$$C = (5.5\mu A \cdot t_{DELAY}) / 1.28V$$

A 10nF capacitor results in approximately 2.3ms of delay.

Layout Hints

The high speed operation of the LT1947 mandates careful attention to layout for proper performance. Be sure to keep input capacitor C_1 as close as possible to the IC and minimize trace area and length at the SW and FB pins. Always use a ground plane under the switching regulator to minimize interplane coupling. Figure 2 shows the recommended component placement.

The exposed pad of the MSE package must be soldered to the PCB and electrically connected to ground. Thermal vias to a large ground plane will lower the thermal resistance.

Soft-Start

For applications requiring soft-start, a circuit consisting of R_{SS} and C_{SS} tied to the SHDN pin can be used, as shown in Figure 3. For a combination of 33.2k/33nF, AV_{DD} rises to its final value in approximately 3ms.
