

## ABSOLUTE MAXIMUM RATINGS (Notes 1 and 2)

### Terminal Voltage

$V_{CC}$  ..... -0.3V to 6.0V  
 $V_{BATT}$  ..... -0.3V to 6.0V  
 All Other Inputs ..... -0.3V to ( $V_{OUT} + 0.3V$ )

### Input Current

$V_{CC}$  ..... 200mA  
 $V_{BATT}$  ..... 50mA  
 GND ..... 20mA

$V_{OUT}$  Output Current ..... Short-Circuit Protected

Power Dissipation ..... 500mW

### Operating Temperature Range

LTC690/91/94/95C ..... 0°C to 70°C

LTC690/91/94/95I ..... -40°C to 85°C

LTC690M ..... -55°C to 125°C

Storage Temperature Range ..... -65°C to 150°C

Lead Temperature (Soldering, 10 sec.) ..... 300°C

## PACKAGE/ORDER INFORMATION (Note 3)

# ELECTRICAL CHARACTERISTICS

The ● denotes specifications which apply over the operating temperature range, otherwise specifications are at  $T_A = 25^\circ\text{C}$ .  $V_{CC}$  = full operating range,  $V_{BATT} = 2.8\text{V}$ , unless otherwise noted.

| OSC IN Frequency with External Capacitor                                                  | OSC SEL = 0V, $C_{OSC} = 47\text{pF}$                                                                          |        |                                      | 4          |          | $\text{kHz}$  |

**Note 1:** Absolute Maximum Ratings are those values beyond which the life of device may be impaired.

**Note 2:** All voltage values are with respect to GND.

**Note 3:** For military temperature range parts or for the LTC692 and LTC693, consult the factory.

**Note 4:** The output pins of BATT ON,  $\overline{\text{LOW LINE}}$ ,  $\overline{\text{PFO}}$ ,  $\overline{\text{WDO}}$ ,  $\overline{\text{RESET}}$  and  $\overline{\text{RESET}}$  have weak internal pull-ups of typically  $3\mu\text{A}$ . However, external pull-up resistors may be used when higher speed is required.

**Note 5:** The LTC690 and LTC691 have minimum reset active time of 35ms (50ms typically) while the LTC694 and LTC695 have longer minimum

reset active time of 140ms (200ms typically). The reset active time of the LTC691 and LTC695 can be adjusted (see Table 2 in Applications Information section).

**Note 6:** The external clock feeding into the circuit passes through the oscillator before clocking the watchdog timer (See Block Diagram). Variation in the time-out period is caused by phase errors which occur when the oscillator divides the external clock by 64. The resulting variation in the time-out period is 64 clocks plus one clock of jitter.

**Note 7:** The input pins of  $\overline{\text{CE IN}}$ , OSC IN and OSC SEL have weak internal pullups which pull to the supply when the input pins are floating.

## BLOCK DIAGRAM

## PIN FUNCTIONS

**$V_{CC}$ :** 5V Supply Input. The  $V_{CC}$  pin should be bypassed with a 0.1 $\mu$ F capacitor.

**$V_{OUT}$ :** Voltage Output for Backed Up Memory. Bypass with a capacitor of 0.1 $\mu$ F or greater. During normal operation,  $V_{OUT}$  obtains power from  $V_{CC}$  through an NMOS power switch, M1, which can deliver up to 50mA and has a typical on resistance of 5 $\Omega$ . When  $V_{CC}$  is lower than  $V_{BATT}$ ,  $V_{OUT}$  is internally switched to  $V_{BATT}$ . If  $V_{OUT}$  and  $V_{BATT}$  are not used, connect  $V_{OUT}$  to  $V_{CC}$ .

**$V_{BATT}$ :** Back-Up Battery Input. When  $V_{CC}$  falls below  $V_{BATT}$ , auxiliary power, connected to  $V_{BATT}$ , is delivered to  $V_{OUT}$  through PMOS switch, M2. If back-up battery or auxiliary power is not used,  $V_{BATT}$  should be connected to GND.

**GND:** Ground pin.

**BATT ON:** Battery On Logic Output from Comparator C2. BATT ON goes low when  $V_{OUT}$  is internally connected to  $V_{CC}$ . The output typically sinks 35mA and can provide base drive for an external PNP transistor to increase the output current above the 50mA rating of  $V_{OUT}$ . BATT ON goes high when  $V_{OUT}$  is internally switched to  $V_{BATT}$ .

**PFI:** Power Failure Input. PFI is the noninverting input to the power-fail comparator, C3. The inverting input is internally connected to a 1.3V reference. The power failure output remains high when PFI is above 1.3V and goes low when PFI is below 1.3V. Connect PFI to GND or  $V_{OUT}$  when C3 is not used.

## PIN FUNCTIONS

**PFO:** Power Failure Output from C3.  $\overline{\text{PFO}}$  remains high when PFI is above 1.3V and goes low when PFI is below 1.3V. When  $V_{\text{CC}}$  is lower than  $V_{\text{BATT}}$ , C3 is shut down and  $\overline{\text{PFO}}$  is forced low.

**RESET:** Logic Output for  $\mu\text{P}$  Reset Control. Whenever  $V_{\text{CC}}$  falls below either the reset voltage threshold (4.65V, typically) or  $V_{\text{BATT}}$ ,  $\overline{\text{RESET}}$  goes active low. After  $V_{\text{CC}}$  returns to 5V, reset pulse generator forces  $\overline{\text{RESET}}$  to remain active low for a minimum of 35ms for the LTC690/LTC691 (140ms for the LTC694/LTC695). When the watchdog timer is enabled but not serviced prior to a preset time-out period, reset pulse generator also forces  $\overline{\text{RESET}}$  to active low for a minimum of 35ms for the LTC690/LTC691 (140ms for the LTC694/5) for every preset time-out period (see Figure 11). The reset active time is adjustable on the LTC691/LTC695. An external push-button reset can be used in connection with the  $\overline{\text{RESET}}$  output. See Push-Button Reset in Applications Information section.

**RESET:** RESET is an active high logic output. It is the inverse of  $\overline{\text{RESET}}$ .

**LOW LINE:** Logic Output from Comparator C1.  $\overline{\text{LOW LINE}}$  indicates a low line condition at the  $V_{\text{CC}}$  input. When  $V_{\text{CC}}$  falls below the reset voltage threshold (4.65V typically),  $\overline{\text{LOW LINE}}$  goes low. As soon as  $V_{\text{CC}}$  rises above the reset voltage threshold,  $\overline{\text{LOW LINE}}$  returns high (see Figure 1).  $\overline{\text{LOW LINE}}$  goes low when  $V_{\text{CC}}$  drops below  $V_{\text{BATT}}$  (see Table 1).

**WDI:** Watchdog Input, WDI, is a three level input. Driving WDI either high or low for longer than the watchdog time-out period, forces both  $\overline{\text{RESET}}$  and  $\overline{\text{WDO}}$  low. Floating WDI disables the watchdog timer. The timer resets itself with each transition of the watchdog input (see Figure 11).

**WDO:** Watchdog Logic Output. When the watchdog input remains either high or low for longer than the watchdog time-out period,  $\overline{\text{WDO}}$  goes low.  $\overline{\text{WDO}}$  is set high whenever there is a transition on the WDI pin, or  $\overline{\text{LOW LINE}}$  goes low. The watchdog timer can be disabled by floating WDI (see Figure 11).

**CE IN:** Logic input to the Chip Enable gating circuit.  $\overline{\text{CE IN}}$  can be derived from microprocessor's address line and/or decoder output. See Applications Information section and Figure 5 for additional information.

**CE OUT:** Logic Output on the Chip Enable Gating Circuit. When  $V_{\text{CC}}$  is above the reset voltage threshold,  $\overline{\text{CE OUT}}$  is a buffered replica of  $\overline{\text{CE IN}}$ . When  $V_{\text{CC}}$  is below the reset voltage threshold  $\overline{\text{CE OUT}}$  is forced high (see Figure 5).

**OSC SEL:** Oscillator Selection Input. When OSC SEL is high or floating, the internal oscillator sets the reset active time and watchdog time-out period. Forcing OSC SEL low, allows OSC IN be driven from an external clock signal or external capacitor be connected between OSC IN and GND.

**OSC IN:** Oscillator Input. OSC IN can be driven by an external clock signal or external capacitor can be connected between OSC IN and GND when OSC SEL is forced low. In this configuration the nominal reset active time and watchdog time-out period are determined by the number of clocks or set by the formula (see Applications Information section). When OSC SEL is high or floating, the internal oscillator is enabled and the reset active time is fixed at 50ms typical for the LTC691 and 200ms typical for the LTC695. OSC IN selects between the 1.6 seconds and 100ms typical watchdog time-out periods. In both cases, the time-out period immediately after a reset is 1.6 seconds typical.

## APPLICATIONS INFORMATION

### Microprocessor Reset

The LTC690 family uses a bandgap voltage reference and a precision voltage comparator C1 to monitor the 5V supply input on  $V_{CC}$  (see Block Diagram). When  $V_{CC}$  falls below the reset voltage threshold, the  $\overline{\text{RESET}}$  output is forced to active low state. The reset voltage threshold accounts for a 5% variation on  $V_{CC}$ , so the  $\overline{\text{RESET}}$  output becomes active low when  $V_{CC}$  falls below 4.75V (4.65V typical). On power-up, the  $\overline{\text{RESET}}$  signal is held active low for a minimum of 35ms for the LTC690/LTC691 (140ms for the LTC694/LTC695) after reset voltage threshold is reached to allow the power supply and microprocessor to stabilize. The reset active time is adjustable on the LTC691/LTC695. On power-down, the  $\overline{\text{RESET}}$  signal remains active low even with  $V_{CC}$  as low as 1V. This capability helps hold the microprocessor in stable shutdown condition. Figure 1 shows the timing diagram of the  $\overline{\text{RESET}}$  signal.

The precision voltage comparator, C1, typically has 40mV of hysteresis which ensures that glitches at  $V_{CC}$  pin do not activate the  $\overline{\text{RESET}}$  output. Response time is typically 10 $\mu$ s. To help prevent mistripping due to transient loads,  $V_{CC}$  pin should be bypassed with a 0.1 $\mu$ F capacitor with the leads trimmed as short as possible.

The LTC691 and LTC695 have two additional outputs:  $\overline{\text{RESET}}$  and  $\overline{\text{LOW LINE}}$ .  $\overline{\text{RESET}}$  is an active high output and is the inverse of  $\overline{\text{RESET}}$ .  $\overline{\text{LOW LINE}}$  is the output of the precision voltage comparator C1. When  $V_{CC}$  falls below

the reset voltage threshold,  $\overline{\text{LOW LINE}}$  goes low.  $\overline{\text{LOW LINE}}$  returns high as soon as  $V_{CC}$  rises above the reset voltage threshold.

### Battery Switchover

The battery switchover circuit compares  $V_{CC}$  to the  $V_{BATT}$  input, and connects  $V_{OUT}$  to whichever is higher. When  $V_{CC}$  rises to 70mV above  $V_{BATT}$ , the battery switchover comparator, C2, connects  $V_{OUT}$  to  $V_{CC}$  through a charge pumped NMOS power switch, M1. When  $V_{CC}$  falls to 50mV above  $V_{BATT}$ , C2 connects  $V_{OUT}$  to  $V_{BATT}$  through a PMOS switch, M2. C2 has typically 20mV of hysteresis to prevent spurious switching when  $V_{CC}$  remains nearly equal to  $V_{BATT}$ . The response time of C2 is approximately 20 $\mu$ s.

During normal operation, the LTC690 family uses a charge pumped NMOS power switch to achieve low dropout and low supply current. This power switch can deliver up to 50mA to  $V_{OUT}$  from  $V_{CC}$  and has a typical on resistance of 5 $\Omega$ . The  $V_{OUT}$  pin should be bypassed with a capacitor of 0.1 $\mu$ F or greater to ensure stability. Use of a larger bypass capacitor is advantageous for supplying current to heavy transient loads.

When operating currents larger than 50mA are required from  $V_{OUT}$ , or a lower dropout ( $V_{CC} - V_{OUT}$  voltage differential) is desired, the LTC691 and LTC695 should be used. These products provide BATT ON output to drive the base

Figure 1. Reset Active Time

## APPLICATIONS INFORMATION

of external PNP transistor (Figure 2). If higher currents are needed with the LTC690 and LTC694, a high current Schottky diode can be connected from the  $V_{CC}$  pin to the  $V_{OUT}$  pin to supply the extra current.

Figure 2. Using BATT ON to Drive External PNP Transistor

The LTC690 family is protected for safe area operation with short-circuit limit. Output current is limited to approximately 200mA. If the device is overloaded for long period of time, thermal shutdown turns the power switch off until the device cools down. The threshold temperature for thermal shutdown is approximately 155°C with about 10°C of hysteresis which prevents the device from oscillating in and out of shutdown.

The PNP switch used in competitive devices was not chosen for the internal power switch because it injects unwanted current into the substrate. This current is collected by the  $V_{BATT}$  pin in competitive devices and adds to the charging current of the battery which can damage lithium batteries. The LTC690 family uses a charge pumped NMOS power switch to eliminate unwanted charging current while achieving low dropout and low supply current. Since no current goes to the substrate, the current collected by  $V_{BATT}$  pin is strictly junction leakage.

A 125Ω PMOS switch connects the  $V_{BATT}$  input to  $V_{OUT}$  in battery back-up mode. The switch is designed for very low dropout voltage (input-to-output differential). This feature is advantageous for low current applications such as battery back-up in CMOS RAM and other low power CMOS circuitry. The supply current in battery back-up mode is 1µA maximum.

The operating voltage at the  $V_{BATT}$  pin ranges from 2.0V to 4.25V. High value capacitors, such as electrolytic or farad-

size double layer capacitors, can be used for short term memory back-up instead of a battery. The charging resistor for both capacitors and rechargeable batteries should be connected to  $V_{OUT}$  since this eliminates the discharge path that exists when the resistor is connected to  $V_{CC}$  (Figure 3).

Figure 3. Charging External Battery Through  $V_{OUT}$

### Replacing the Back-Up Battery

When changing the back-up battery with system power on, spurious resets can occur while battery is removed due to battery standby current. Although battery standby current is only a tiny leakage current, it can still charge up the stray capacitance on the  $V_{BATT}$  pin. The oscillation cycle is as follows: When  $V_{BATT}$  reaches within 50mV of  $V_{CC}$ , the LTC690 switches to battery back-up.  $V_{OUT}$  pulls  $V_{BATT}$  low and the device goes back to normal operation. The leakage current then charges up the  $V_{BATT}$  pin again and the cycle repeats.

If spurious resets during battery replacement pose no problems, then no action is required. Otherwise, a resistor from  $V_{BATT}$  to GND will hold the pin low while changing the battery. For example, the battery standby current is 1µA maximum over temperature and the external resistor required to hold  $V_{BATT}$  below  $V_{CC}$  is:

$$R \leq \frac{V_{CC} - 50\text{mV}}{1\mu\text{A}}$$

With  $V_{CC} = 4.5\text{V}$ , a 4.3M resistor will work. With a 3V battery, this resistor will draw only 0.7µA from the battery, which is negligible in most cases.

## APPLICATIONS INFORMATION

If battery connections are made through long wires, a  $10\Omega$  to  $100\Omega$  series resistor and a  $0.1\mu\text{F}$  capacitor are recommended to prevent any overshoot beyond  $V_{\text{CC}}$  due to the lead inductance (Figure 4).

**Figure 4.  $10\Omega/0.1\mu\text{F}$  Combination Eliminates Inductive Overshoot and Prevents Spurious Resets During Battery Replacement**

Table 1 shows the state of each pin during battery back-up. When the battery switchover section is not used, connect  $V_{\text{BATT}}$  to GND and  $V_{\text{OUT}}$  to  $V_{\text{CC}}$ .

### Memory Protection

The LTC691 and LTC695 include memory protection circuitry that ensures the integrity of the data in memory by preventing write operations when  $V_{\text{CC}}$  is at invalid level. Two additional pins,  $\overline{\text{CE IN}}$  and  $\overline{\text{CE OUT}}$ , control the Chip Enable or Write inputs of CMOS RAM. When  $V_{\text{CC}}$  is 5V,  $\overline{\text{CE OUT}}$  follows  $\overline{\text{CE IN}}$  with a typical propagation delay of 20ns. When  $V_{\text{CC}}$  falls below the reset voltage threshold or  $V_{\text{BATT}}$ ,  $\overline{\text{CE OUT}}$  is forced high, independent of  $\overline{\text{CE IN}}$ .  $\overline{\text{CE}}$

OUT is an alternative signal to drive the  $\overline{\text{CE}}$ ,  $\overline{\text{CS}}$ , or  $\overline{\text{Write}}$  input of battery-backed up CMOS RAM.  $\overline{\text{CE OUT}}$  can also be used to drive the Store or Write input of an EEPROM, EARM or NOVRAM to achieve similar protection. Figure 5 shows the timing diagram of  $\overline{\text{CE IN}}$  and  $\overline{\text{CE OUT}}$ .

$\overline{\text{CE IN}}$  can be derived from the microprocessor's address decoder output. Figure 6 shows a typical nonvolatile CMOS RAM application.

Memory protection can also be achieved with the LTC690 and LTC694 by using RESET as shown in Figure 7.

**Table 1. Input and Output Status in Battery Back-Up Mode**

| SIGNAL                     | STATUS                                                                              |
|----------------------------|-------------------------------------------------------------------------------------|
| $V_{\text{CC}}$            | C2 monitors $V_{\text{CC}}$ for active switchover.                                  |
| $V_{\text{OUT}}$           | $V_{\text{OUT}}$ is connected to $V_{\text{BATT}}$ through an internal PMOS switch. |
| $V_{\text{BATT}}$          | The supply current is $1\mu\text{A}$ maximum.                                       |

Figure 9. Monitoring *Regulated* DC Supply with the LTC690's Power-Fail Comparator

### Power-Fail Warning

The LTC690 family generates a Power Failure Output (PFO) for early warning of failure in the microprocessor's power supply. This is accomplished by comparing the Power Failure Input (PFI) with an internal 1.3V reference. PFO goes low when the voltage at the PFI pin is less than 1.3V. Typically PFI is driven by an external voltage divider (R1 and R2 in Figures 8 and 9) which senses either an unregulated DC input or a regulated 5V output. The voltage divider ratio can be chosen such that the voltage at the PFI pin falls below 1.3V several milliseconds before the 5V supply falls below the maximum reset voltage threshold 4.75V. PFO is normally used to interrupt the microprocessor to execute shutdown procedure between PFO and RESET or RESET.

The power-fail comparator, C3, does not have hysteresis. Hysteresis can be added however, by connecting a resistor between the PFO output and the noninverting PFI input pin as shown in Figures 8 and 9. The upper and lower trip points in the comparator are established as follows:

When PFO output is low, R3 sinks current from the summing junction at the PFI pin.

$$V_H = 1.3V \left( 1 + \frac{R1}{R2} + \frac{R1}{R3} \right)$$

When PFO output is high, the series combination of R3 and R4 source current into the PFI summing junction.

$$V_L = 1.3V \left( 1 + \frac{R1}{R2} - \frac{(5V - 1.3V)R1}{1.3V(R3 + R4)} \right)$$

$$\text{Assuming } R4 \ll R3, V_{HYSTERESIS} = 5V \frac{R1}{R3}$$

**Example 1:** The circuit in Figure 8 demonstrates the use of the power-fail comparator to monitor the unregulated power supply input. Assuming the rate of decay of the supply input  $V_{IN}$  is 100mV/ms and the total time to execute a shutdown procedure is 8ms. Also the noise of  $V_{IN}$  is 200mV. With these assumptions in mind, we can reasonably set  $V_L = 7.5V$  which is 1.25V greater than the sum of maximum reset voltage threshold and the dropout voltage

## APPLICATIONS INFORMATION

of LT1086-5 (4.75V + 1.5V) and  $V_{HYSTERESIS} = 850\text{mV}$ .

$$V_{HYSTERESIS} = 5V \frac{R1}{R3} = 850V$$

$$R3 \approx 5.88 R1$$

Choose  $R3 = 300\text{k}$  and  $R1 = 51\text{k}$ . Also select  $R4 = 10\text{k}$  which is much smaller than  $R3$ .

$$7.5V = 1.3V \left( 1 + \frac{51\text{k}}{R2} - \frac{(5V - 1.3V)51\text{k}}{1.3V(310\text{k})} \right)$$

$R2 = 9.7\text{k}\Omega$ , Choose nearest 5% resistor  $10\text{k}$  and recalculate  $V_L$ ,

$$V_L = 1.3V \left( 1 + \frac{51\text{k}}{10\text{k}} - \frac{(5V - 1.3V)51\text{k}}{1.3V(310\text{k})} \right) = 7.32V$$

$$V_H = 1.3V \left( 1 + \frac{51\text{k}}{10\text{k}} + \frac{51\text{k}}{300\text{k}} \right) = 8.151V$$

$$\frac{(7.32V - 6.25V)}{100\text{mV/ms}} = 10.7\text{ms}$$

$$V_{HYSTERESIS} = 8.151V - 7.32V = 831\text{mV}$$

The 10.7ms allows enough time to execute shutdown procedure for microprocessor and 831mV of hysteresis would prevent PFO from going low due to the noise of  $V_{IN}$ .

**Example 2:** The circuit in Figure 9 can be used to measure the regulated 5V supply to provide early warning of power failure. Because of variations in the PFI threshold, this circuit requires adjustment to ensure the PFI comparator trips before the reset threshold is reached. Adjust  $R5$  such that the PFO output goes low when the  $V_{CC}$  supply reaches the desired level (e.g., 4.85V).

### Monitoring the Status of the Battery

C3 can also monitor the status of the memory back-up battery (Figure 10). If desired, the  $\overline{\text{CE}}_{OUT}$  can be used to apply a test load to the battery. Since  $\overline{\text{CE}}_{OUT}$  is forced high in battery back-up mode, the test load will not be applied to the battery while it is in use, even if the microprocessor is not powered.

Figure 10. Back-Up Battery Monitor with Optional Test Load

### Watchdog Timer

The LTC690 family provides a watchdog timer function to monitor the activity of the microprocessor. If the microprocessor does not toggle the Watchdog Input (WDI) within a selected time-out period,  $\overline{\text{RESET}}$  is forced to active low for a minimum of 35ms for the LTC690/LTC691 (140ms for the LTC694/LTC695). The reset active time is adjustable on the LTC691/LTC695. Since many systems can not service the watchdog timer immediately after a reset, the LTC691 and LTC695 have longer time-out period (1.0 second minimum) right after a reset is issued. The normal time-out period (70ms minimum) becomes effective following the first transition of WDI after  $\overline{\text{RESET}}$  is inactive. The watchdog time-out period is fixed at 1.0 second minimum on the LTC690 and LTC694. Figure 11 shows the timing diagram of watchdog time-out period and reset active time. The watchdog time-out period is restarted as soon as  $\overline{\text{RESET}}$  is inactive. When either a high-to-low or low-to-high transition occurs at the WDI pin prior to time-out, the watchdog time is reset and begins to time out again. To ensure the watchdog time does not time out, either a high-to-low or low-to-high transition on the WDI pin must occur at or less than the minimum time-out period. If the input to the WDI pin remains either high or low, reset pulses will be issued every 1.6 seconds typically. The watchdog time can be deactivated by floating the WDI pin. The timer is also disabled when  $V_{CC}$  falls below the reset voltage threshold or  $V_{BATT}$ .

## APPLICATIONS INFORMATION

The LTC691 and LTC695 provide an additional output (Watchdog Output,  $\overline{\text{WDO}}$ ) which goes low if the watchdog timer is allowed to time out and remains low until set high by the next transition on the WDI pin.  $\overline{\text{WDO}}$  is also set high when  $V_{CC}$  falls below the reset voltage threshold or  $V_{BATT}$ .

The LTC691 and LTC695 have two additional pins OSC SEL and OSC IN, which allow reset active time and watchdog time-out period to be adjusted per Table 2. Several configurations are shown in Figure 12.

OSC IN can be driven by an external clock signal or an external capacitor can be connected between OSC IN and

GND when OSC SEL is forced low. In these configurations, the nominal reset active time and watchdog time-out period are determined by the number of clocks or set by the formula in Table 2. When OSC SEL is high or floating, the internal oscillator is enabled and the reset active time is fixed at 35ms minimum for the LTC691 and 140ms minimum for the LTC695. OSC IN selects between the 1 second and 70ms minimum normal watchdog time-out periods. In both cases, the time-out period immediately after a reset is at least 1 second.

\*The nominal internal frequency is 10.24kHz. The nominal oscillator frequency with external capacitor is  $f_{\text{OSC}} (\text{Hz}) = \frac{184,000}{C(\text{pF}) \cdot 1025}$

### Push-Button Reset

The LTC690 family does not provide a logic input for direct connection to a pushbutton. However, a push-button in series with a 100Ω resistor connected to the  $\overline{\text{RESET}}$  output pin (Figure 13) provides an alternative for manual reset. Connecting a 0.1μF capacitor to the  $\overline{\text{RESET}}$  pin debounces the push-button input.

The 100Ω resistor in series with the push-button is required to prevent the ringing, due to the capacitance and lead inductance, from pulling the  $\overline{\text{RESET}}$  pins of the MPU and LTC69X below ground.

If a dedicated pushbutton reset input is desired, the LTC1235 is a good choice (Figure 14). It has all the functions of the LTC695 and provides push-button reset as an extra feature. Its push-button is internally debounced and invokes the normal 200ms reset sequence. This eliminates the need for the 100Ω resistor and 0.1μF capacitor. It also provides a more consistent reset pulse.
