The SP3244E and SP3245E are 3-driver/5-receiver devices ideal for serial ports in battery-powered, portable, or handheld applications such as notebook or handheld computers. SP3244E/3245E transceivers meet the EIA/TIA-232 and ITU-T V.28/V.24 communication protocols for reliable serial communication. The SP3244E/3245E devices feature Exar's proprietary and patented (U.S. 5,306,954) on-board charge pump circuitry that generates  $\pm 5.5\text{V}$  RS-232 voltage levels from a single +3.0V to +5.5V power supply.

The SP3244E/3245E is an ideal choice for power sensitive designs. With the Auto On-Line® Plus enabled the SP3244E/3245E reduces power consumption to a  $1\mu\text{A}$  supply current whenever the transceiver is idle. In shutdown, the internal charge pump and the drivers will shut down. Receivers remain active unless the device is put into manual shutdown using the  $\overline{\text{SHUTDOWN}}$  pin. This feature allows design engineers to address power saving concerns without major design changes.

### Theory Of Operation

The SP3244E/3245E is made up of four basic circuit blocks:

1. Drivers, 2. Receivers, 3. the Exar proprietary charge pump, and 4. Auto On-line® Plus circuitry.

### Drivers

The drivers are inverting level transmitters that convert TTL or CMOS logic levels to 5.0V EIA/TIA-232 levels with an inverted sense relative to the input logic levels. Typically, the RS-232 output voltage swing is +5.4V with no load and +5V minimum fully loaded. The driver outputs are protected against infinite short circuits to ground without degradation in reliability. These drivers comply with the EIA/TIA-232-F and all previous RS-232 versions. Unused driver inputs should be connected to GND or VCC.

The SP3244E/3245E devices operate at this typical data rate when fully loaded. The drivers can guarantee output data rates fully loaded with  $3\text{K}\Omega$  in parallel with  $1000\text{pF}$  (SP3244E), or  $250\text{pF}$  (SP3245E) ensuring compatibility with popular PC-to-PC communication software. The slew rate of the driver output on the SP3244E is internally limited to a maximum of  $30\text{V}/\mu\text{s}$  in order to meet the EIA standards

(EIA RS-232D 2.1.7, Paragraph 5). The slew rate of SP3245E is not limited to enable higher speed data transfers. The transition of the loaded output from HIGH to LOW also meets the monotonic signal transition requirements of the standard.

### Receivers

The receivers convert EIA/TIA-232 signal levels to TTL or CMOS logic output levels. Receivers remain active unless the device is put into manual shutdown using the  $\overline{\text{SHUTDOWN}}$  pin. The non-inverted output of Receiver 2 ( $\overline{\text{R2OUT}}$ ) will continue to be active in all modes, including shutdown.

Since receiver input is usually from a transmission line where long cable lengths and system interference can degrade the signal, the inputs have a typical hysteresis margin of 500mV. This ensures that the receiver is virtually immune to noisy transmission lines. Should an input be left unconnected, an internal  $5\text{K}\Omega$  pull-down resistor to ground will commit the output of the receiver to a HIGH state.

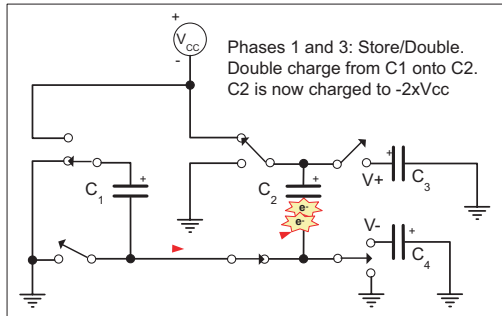

### Highly Efficient Charge Pump

The charge pump is used to generate positive and negative signal voltages for the RS-232 drivers. This enables fully compliant RS-232 and V.28 signals from a single 3.0 or 5.5V power supply.

The charge pumps use four external capacitors to hold and transfer electrical charge. The Exar patented design (US Patent #5,306,954) uses a unique approach compared to older less efficient designs. The pumps use a four-phase voltage shifting technique to attain symmetrical V+ and V- power supplies. An intelligent control oscillator regulates the operation of the charge pump to maintain the proper voltages at maximum efficiency.

### Phase 1

VSS charge store and double the positive terminals of capacitors C1 and C2 are charged from VCC with their negative terminals initially connected to ground. C1+ is then connected to ground and the stored charge from C1- is superimposed onto C2-. Since C2+ is still connected to VCC the voltage potential across capacitor C2 is now  $2 \times V_{\text{CC}}$ .

Patented 5,306,954 (Sipex, inc.)

Charge Pump Phases

**Phase 2**

VSS transfer and invert: Phase two connects the negative terminal of C2 to the VSS storage capacitor and the positive terminal of C2 to ground. This transfers the doubled and inverted ( $V^-$ ) voltage onto C3. Meanwhile, capacitor C1 charged from VCC to prepare it for its next phase.

**Phase 3**

VDD charge store and double: Phase three is identical to the first phase. The positive terminals of capacitors C1 and C2 are charged from Vcc with their negative terminals initially connected to ground. C1+ is then connected to ground and the stored charge from C1- is superimposed onto C2-. Since C2+ is still connected to Vcc the voltage potential across capacitor C2 is now  $2 \times V_{cc}$ .

**Phase 4**

VDD transfer: The fourth phase connects the negative terminal of C2 to ground and the positive terminal of C2 to the VDD storage capacitor. This transfers the doubled ( $V^+$ ) voltage onto C4. Meanwhile, capacitor C1 charged from Vcc to prepare it for its next phase.

The Exar charge pump generates  $V^+$  and  $V^-$  independently from Vcc. Hence in a no-load condition  $V^+$  and  $V^-$  will be symmetrical. Older charge pump approaches generate  $V^+$  and then use part of that stored charge to generate  $V^-$ . Because of inherent losses the magnitude of  $V^-$  will be smaller than  $V^+$  on these older designs.

Under lightly loaded conditions the intelligent pump oscillator maximizes efficiency by running only as needed to maintain  $V^+$  and  $V^-$ . Since interface transceivers often spend much of their time at idle this power-efficient innovation can greatly reduce total power consumption. This improvement is made possible by the independent phase sequence of the Exar charge-pump design.

The clock rate for the charge pump typically operates at greater than 70kHz allowing the pump to run efficiently with small  $0.1\mu\text{F}$  capacitors. Efficient operation depends on rapidly charging and discharging C1 and C2, therefore capacitors should be mounted close to the IC and have low ESR (equivalent series resistance). Inexpensive

surface mount ceramic capacitors (such as are widely used for power-supply decoupling) are ideal for use on the charge pump. The charge pumps are designed to be able to function properly with a wide range of capacitor styles and values. If polarized capacitors are used the positive and negative terminals should be connected as shown on the Typical Operating Circuit.

Capacitance values may be increased if operating at higher Vcc or to provide greater stability as the capacitors age.

**Auto On-Line® Plus Circuitry**

The SP3244E/3245E devices have the advanced Auto On-Line® Plus feature that saves power by turning off the charge pumps and driver outputs when the transceiver inputs are idle for more than 30 seconds.

RS-232 signals use both positive and negative voltages of greater than  $\pm 5\text{V}$  magnitude. Receivers have nominal  $5\text{k}\Omega$  impedance to ground. Even when idle, drivers will maintain output signal voltage creating a continuous current flow. In low power, battery operated devices this constant current drain can decrease battery life significantly.

Auto On-Line® Plus devices may be configured

Receiver 5kΩ Current path to

to emulate the behavior of devices with our earlier Auto On-line® feature. Auto On-Line® Plus puts the device into a low power mode when driver or receiver inputs are idle and re-awakes upon detecting signal transitions. Auto On-Line® puts the device into a low power mode when receiver inputs are left floating and re-awakes when receivers are driven greater than  $\pm 2.7\text{V}$  magnitude by incoming RS-232 signal.

Auto On-Line® Plus provides greater power savings in typical operation because the transceiver will go into low power standby mode unless a communication link is in use. Signals such as CTS, RTS, DTR, DSR, or RI will typically change signal-state to establish handshaking before any actual data-communication takes place. Transitions on these handshake signals will wake up the Auto On-Line® Plus transceiver to prepare it for sending data ( $t_{\text{ONLINE}} = 100\mu\text{s}$  typical).

Receivers remain active to detect incoming signals in Auto On-Line® Plus standby mode. Receiver outputs may be disabled by entering manual shutdown by driving SHUTDOWN pin to logic 0. A special non-inverted receiver output R2OUT remains active in all modes, including SHUTDOWN pin at logic 0.

In some applications if there is a significant delay (greater than  $t_{\text{OFFLINE}}$ ) between the handshaking transitions and the start of data communication the transceiver may enter Auto On-Line® Plus standby mode before data communication begins. The  $t_{\text{OFFLINE}}$  interval is at least 15 seconds and no longer than 60 seconds.

In applications where the transceiver needs to remain active anytime it is connected to live RS-232 signals, even if those signals remain idle for longer than  $t_{\text{OFFLINE}}$ , then the STATUS output may be used to drive the ONLINE pin. The STATUS output pin functions the same in both Auto On-Line® and Auto On-line® Plus devices. STATUS will output logic 1 if any of the receiver inputs are driven greater than  $\pm 2.7\text{V}$  magnitude by incoming RS-232 signals and drives logic 0 if receiver inputs are floating or driven to ground (see page 14). Driving the ONLINE pin with the STATUS output disables Auto On-line® Plus (Forced On-Line) whenever RS-232 voltages are seen on any receiver inputs. If no RS-232 voltages are seen on the receiver inputs the Auto On-Line® Plus transceiver will still activate its charge pump and driver outputs when the driver inputs are active. This allows the transceiver to signal a remote Auto On-Line® or Auto On-Line® Plus, on the other end of the data cable, to wake up. The STATUS output pin remains active in all modes, including SHUTDOWN pin at logic 0. Connecting STATUS output to drive both ONLINE and SHUTDOWN will wake the transceiver if any receiver inputs are driven greater

than  $\pm 2.7\text{V}$  magnitude and put the transceiver into Forced Shutdown mode if all receiver inputs are floating or driven to ground.

### ±15KV ESD PROTECTION

ESD-protection structures are incorporated on all pins to protect against electrostatic discharges encountered during handling and assembly. The driver output and receiver inputs of the SP3244E/3245E have extra protection against static electricity. Exar uses state-of-the-art structures to protect these pins against ESD of  $\pm 15\text{kV}$  without damage. The ESD structures withstand high ESD in all states: normal operation, shutdown, and powered down. After an ESD event, the SP3244E/3245E keep working without latch-up or damage.

ESD protection can be tested in various ways. The transmitter outputs and receiver inputs of the SP3244/3245 are characterized for protection to the following limits:

- $\pm 15\text{kV}$  using the Human Body Model

Packaging Approval:		Drawing No:	
28 PIN TSSOP PACKAGE OUTLINE		28-PIN TSSOP	
By: JL	Date: 11/28/07	Revision: B	Sheet: 1 OF 1

Part number	Temperature range	Package Type
SP3244ECA-L	From 0° to +70°C	28 pin SSOP
SP3244ECY-L	From 0° to +70°C	28 pin TSSOP
SP3244EEA-L	From -40° to +85°C	28 pin SSOP
SP3244EEY-L	From -40° to +85°C	28 pin TSSOP
SP3244EER1-L	From -40° to +85°C	32 pin QFN
SP3245ECA-L	From 0° to +70°C	28 pin SSOP
SP3245ECY-L	From 0° to +70°C	28 pin TSSOP
SP3245EEA-L	From -40° to +85°C	28 pin SSOP
SP3245EEY-L	From -40° to +85°C	28 pin TSSOP
SP3245EER1-L	From -40° to +85°C	32 pin QFN

Available in lead free packaging.

Available in Tape and Reel. To order add "/TR" suffix to part number,

Example: SP3244ECA-L= Standard; SP3244ECA-L/TR =Tape and Reel

DATE	REVISION	DESCRIPTION
10-09-06	M	Legacy Sipex Datasheet
12-15-09	1.0.0	Update to Exar Format. Change revision to 1.0.0. Change driver short circuit current limit from +/-60mA to +/-100mA. Add T <sub>A</sub> = 25°C to test conditions for Transition Region Slew Rate and Mouse Drivability parameters . Delete / remove all reference to IEC ESD protection. Change RX input voltage ABS Maximum Rating from +/-18V to +/-16V.

#### Notice

EXAR Corporation reserves the right to make changes to any products contained in this publication in order to improve design, performance or reliability. EXAR Corporation assumes no representation that the circuits are free of patent infringement. Charts and schedules contained herein are only for illustration purposes and may vary depending upon a user's specific application. While the information in this publication has been carefully checked; no responsibility, however, is assumed for inaccuracies.

EXAR Corporation does not recommend the use of any of its products in life support applications where the failure or malfunction of the product can reasonably be expected to cause failure of the life support system or to significantly affect its safety or effectiveness. Products are not authorized for use in such applications unless EXAR Corporation receives, in writing, assurances to its satisfaction that: (a) the risk of injury or damage has been minimized ; (b) the user assumes all such risks; (c) potential liability of EXAR Corporation is adequately protected under the circumstances.
