**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LTC3428E is guaranteed to meet performance specifications from  $0^\circ\text{C}$  to  $70^\circ\text{C}$ . Specifications over the  $-40^\circ\text{C}$  to  $85^\circ\text{C}$  operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:** Specification is guaranteed by design and not 100% tested in production.

**Note 4:** This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed  $125^\circ\text{C}$  when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

## PIN FUNCTIONS

**PGNDA, PGNDB (Pins 1, 10, 11 (Exposed Pad)):** Power Ground for the IC. Tie directly to local ground plane.

**SWA (Pin 2), SWB (Pin 9):** Phase B and Phase A Switch Pins. The inductor and Schottky diodes for each phase are connected to these pins. Minimize trace length to reduce EMI.

**V<sub>OUT</sub> (Pin 3):** Power Supply Output and Bootstrapped Power Source for the IC. Connect low ESR output filter capacitors from this pin to the ground plane.

**SHDN (Pin 4):** Shutdown Pin. Grounding this pin shuts down the IC. Connect to a voltage greater than 1.5V to enable.

**V<sub>C</sub> (Pin 5):** Error Amp Output. A frequency compensation network is connected to this pin to compensate the boost converter loop.

**FB (Pin 6):** Feedback Pin. A resistor divider from V<sub>OUT</sub> is connected here to set the output voltage according to  $V_{OUT} = 1.243 \cdot (1 + R1 / R2)$

**AGND (Pin 7):** Signal Ground for the IC. Connect to ground plane near feedback resistor divider.

**V<sub>IN</sub> (Pin 8):** Input Supply Pin. Bypass V<sub>IN</sub> with a low ESR ceramic capacitor of at least 4.7μF. X5R and X7R dielectrics are preferred for their superior voltage and temperature characteristics.

## BLOCK DIAGRAM

## APPLICATIONS INFORMATION

### DETAILED DESCRIPTION

The LTC3428 provides high efficiency, low noise power for high current boost applications. A current mode architecture with adaptive slope compensation provides both simple loop compensation as well as excellent transient response. The low  $R_{DS(ON)}$  switches provide the pulse width modulation control at high efficiency.

**Oscillator:** The per phase switching frequency is internally set to a nominal value of 1MHz.

**Current Sensing:** Lossless current sensing converts the peak current signal to a voltage which is summed with the internal slope compensation. This summed signal is then compared with the error amplifier output to provide a peak current command for the PWM. Slope compensation is internal to the IC and adapts to changes to the input voltage, allowing the converter to provide the necessary degree of slope compensation without causing a loss in phase margin in the loop characteristic.

**Error Amplifier:** The error amplifier is a transconductance amplifier with a transconductance ( $g_m$ ) = 1/5.9k $\Omega$ . A simple compensation network is placed from  $V_C$  to ground. The internal 5pF capacitor between  $V_C$  and ground will often simplify the external network to a simple R-C combination. The internal 1.243V reference voltage is compared to the voltage on FB to generate an error signal at the output of the error amplifier ( $V_C$ ). A voltage divider from  $V_{OUT}$  to ground programs the output voltage from 1.6V to 5.25V using the equation:

$$V_{OUT} = 1.243V \cdot (1 + R1/R2)$$

**Soft-Start:** Where R1 and R2 are shown in Figure 3. An internal soft-start of approximately 1.5ms is provided. This is a ramp signal that limits the peak current until the internal soft-start voltage is greater than the internal current limit voltage. The internal soft-start capacitor is automatically discharged when the part is in shutdown mode.

**Current Limit:** The current limit comparator in each phase will shut off the N-channel MOSFET switches once the current exceeds the current limit threshold, nominally 2.5A. The current limit delay to output is typically 40ns. The current signal leading edge is blanked for 40ns to enhance noise rejection.

**Anti-Ringing Control:** The antiringing control places an impedance across the inductor of each phase to damp the high frequency ringing on the SWA, SWB pins during discontinuous mode operation. The LC ringing on the switch pin due to the inductor and switch pin capacitance is low energy, but can cause EMI radiation.

### 2-Phase Operation

The LTC3428 uses a two-phase architecture, rather than the conventional single phase architecture used in most other boost converters. The two phases are spaced 180° apart. Two phase operation doubles the output ripple frequency and provides a significant reduction in output ripple current, minimizing the stress on the output capacitor. Inductor (input) peak and ripple currents are also reduced, allowing for the use of smaller, lower cost inductors. The greatly reduced output ripple current also minimizes the output capacitance requirement. The higher frequency output ripple is easier to filter for lower noise applications.

Input and output current comparisons for single and 2-phase converters are illustrated in Figures 1 and 2.

For the example illustrated in Figure 2, peak-to-peak output ripple current was reduced by 85%, from 4.34A, to 0.64A, and peak inductor current was reduced by 53%, from 4.34A to 2.02A. These reductions enable the use of low profile, smaller valued inductors and output capacitors as compared to a single-phase design.

**Figure 1. Input Ripple Current Comparison Between Single Phase and Two-Phase Boost Converters with a 2A Load and 50% Duty Cycle**

## APPLICATIONS INFORMATION

**Figure 2. Output Ripple Current Comparison Between Single Phase and Two Phase Boost Converters with a 2A Load and 50% Duty Cycle**

## COMPONENT SELECTION

### Inductor Selection

The high frequency operation of the LTC3428 allows for the use of small surface mount inductors. The inductor ripple current is typically set to between 20% and 40% of the maximum inductor current. For a given set of conditions, the inductance is given as follows:

$$L \geq \frac{V_{IN(MIN)} \cdot (V_{OUT} - V_{IN(MIN)})}{R \cdot V_{OUT}}, L > 2\mu H$$

where:

$R$  = Allowable inductor current ripple (Amps P-P)

$V_{IN(MIN)}$  = Minimum input voltage (V)

$V_{OUT}$  = Output voltage (V)

For high efficiency, the inductor should have a high frequency core material, such as ferrite, to reduce core losses. The inductor should have a low ESR (equivalent series resistance) to reduce  $I^2R$  losses and must be able to handle the peak inductor current without saturating. Use of a toroid, pot core, or shielded bobbin inductor will minimize radiated noise. See Table 1 for a list of inductor manufacturers. Some example inductor part types are: Coilcraft 1608 and 3316 series, Murata LQH55D series,

Sumida CDRH4D22C/LD or CDRH5D28 series, Toko FDV0630 or D62CB series.

### Output Capacitor Selection

The minimum value of the capacitor is set to reduce the output ripple voltage due to charging and discharging the capacitor each cycle. The steady state ripple due to this charging is given by:

$$V_{RIPPLE(C)} = \frac{1}{2} \cdot \frac{I_{PEAK} \cdot (V_{OUT} - V_{IN(MIN)})}{C_{OUT} \cdot V_{OUT} \cdot f}$$

where:  $I_{PEAK}$  = Peak inductor current (A)

The equivalent series resistance (ESR) of the output capacitor will contribute another term to output voltage ripple. Ripple voltage due to capacitor ESR is:

$$V_{RIPPLE(ESR)} = I_{PEAK} \cdot R_{ESR(C)}$$

where:

$R_{ESR(C)}$  = Capacitor ESR

The ESL (Equivalent Series Inductance) is another capacitor characteristic that needs to be minimized. ESL will be minimized by using small surface mount ceramic capacitors, placed as close to the  $V_{OUT}$  pin as possible.

### Input Capacitor Selection

Since the  $V_{IN}$  pin directly powers most of the internal circuitry, it is recommended to place at least a 4.7 $\mu F$ , low ESR bypass capacitor between  $V_{IN}$  and AGND, as close to the IC as possible. See Table 2 for a list of capacitor manufacturers.

### Output Diode Selection

For high efficiency, a fast switching diode with low reverse leakage and a low forward drop is required. Schottky diodes are recommended for their low forward drop and fast switching times. When selecting a diode, it is important to remember that the average diode current in a boost converter is equal to the average load current:  $I_D = I_{LOAD}$

When selecting a diode, make sure that the peak forward current and average power dissipation ratings meet the application requirements. See Table 3 for a list of Schottky diode manufacturers. Example diodes are Philips PMEG1020, PMEG2010, On-Semi MBRA210, IR 10BQ015, Microsemi UPS120E, UPS315.

### Thermal Considerations

To deliver maximum power, it is necessary to provide a good thermal path to dissipate the heat generated within the LTC3428's package. The large thermal pad on the IC underside can accomplish this requirement. Use multiple PC board vias to conduct heat from the IC and to a copper plane that has as much area as possible.

If the junction temperature gets too high, the LTC3428 will stop all switching until the junction temperature drops to safe levels. The typical over temperature threshold is 150°C.

### Closing the Feedback Loop

The LTC3428 uses current mode control with internal, adaptive slope compensation. Current mode control eliminates the 2nd order pole in the loop response of voltage mode converters due to the inductor and output capacitor, simplifying it to a single pole response. The product of the modulator control to output DC gain and the error amp open-loop gain equals the DC gain of the system.

$$G_{DC} = G_{CONTROL} \cdot G_{EA} \cdot \frac{V_{REF}}{V_{OUT}}$$

$$G_{CONTROL} = \frac{2 \cdot V_{IN}}{I_{OUT}}$$

$$G_{EA} \approx 100$$

The output filter pole is given by:

$$f_{POLE} = \frac{I_{OUT}}{\pi \cdot V_{OUT} \cdot C_{OUT}} \text{ Hz}$$

where  $C_{OUT}$  is the output filter capacitor value. The output filter zero is given by:

$$f_{ZERO} = \frac{1}{2 \cdot \pi \cdot R_{ESR} \cdot C_{OUT}} \text{ Hz}$$

where  $R_{ESR}$  is the output capacitor equivalent series resistance.

A complication of the boost converter topology is the right half plane (RHP) zero and is given by:

$$f_{RHP} = \frac{V_{IN}^2 \cdot R_O}{2 \cdot \pi \cdot L \cdot V_O^2} \text{ Hz}$$

The equations for the loop dynamics are as follow:

$$f_{\text{POLE1}} \approx \frac{1}{2 \cdot \pi \cdot 400\text{e}6 \cdot C_{C1}}$$

$$f_{ZERO1} \approx \frac{1}{2 \cdot \pi \cdot R_Z \cdot C_{C1}}$$

$$f_{\text{ZER02}} \approx \frac{1}{2 \cdot \pi \cdot R_7 \cdot (C_{\text{C2}} + 5\text{pF})}$$
