4 Smart shutdown function

The STGIPS20K60 integrates a comparator for fault sensing purposes. The comparator has an internal voltage reference Vref connected to the inverting input, while the non-inverting input, available on pin (CIN), can be connected to an external shunt resistor in order to implement a simple over-current protection function. When the comparator triggers, the device is set in shutdown state and both its outputs are set to low-level leading the halfbridge in tri-state. In the common overcurrent protection architectures the comparator output is usually connected to the shutdown input through a RC network, in order to provide a mono-stable circuit, which implements a protection time that follows the fault condition. Our smart shutdown architecture allows to immediately turn-off the output gate driver in case of overcurrent, the fault signal has a preferential path which directly switches off the outputs. The time delay between the fault and the outputs turn-off is no more dependent on the RC values of the external network connected to the shutdown pin. At the same time the DMOS connected to the open-drain output (pin $\overline{SD}$/OD) is turned on by the internal logic which holds it on until the shutdown voltage is lower than the logic input lower threshold (Vil). Finally the smart shutdown function provides the possibility to increase the real disable time without increasing the constant time of the external RC network.

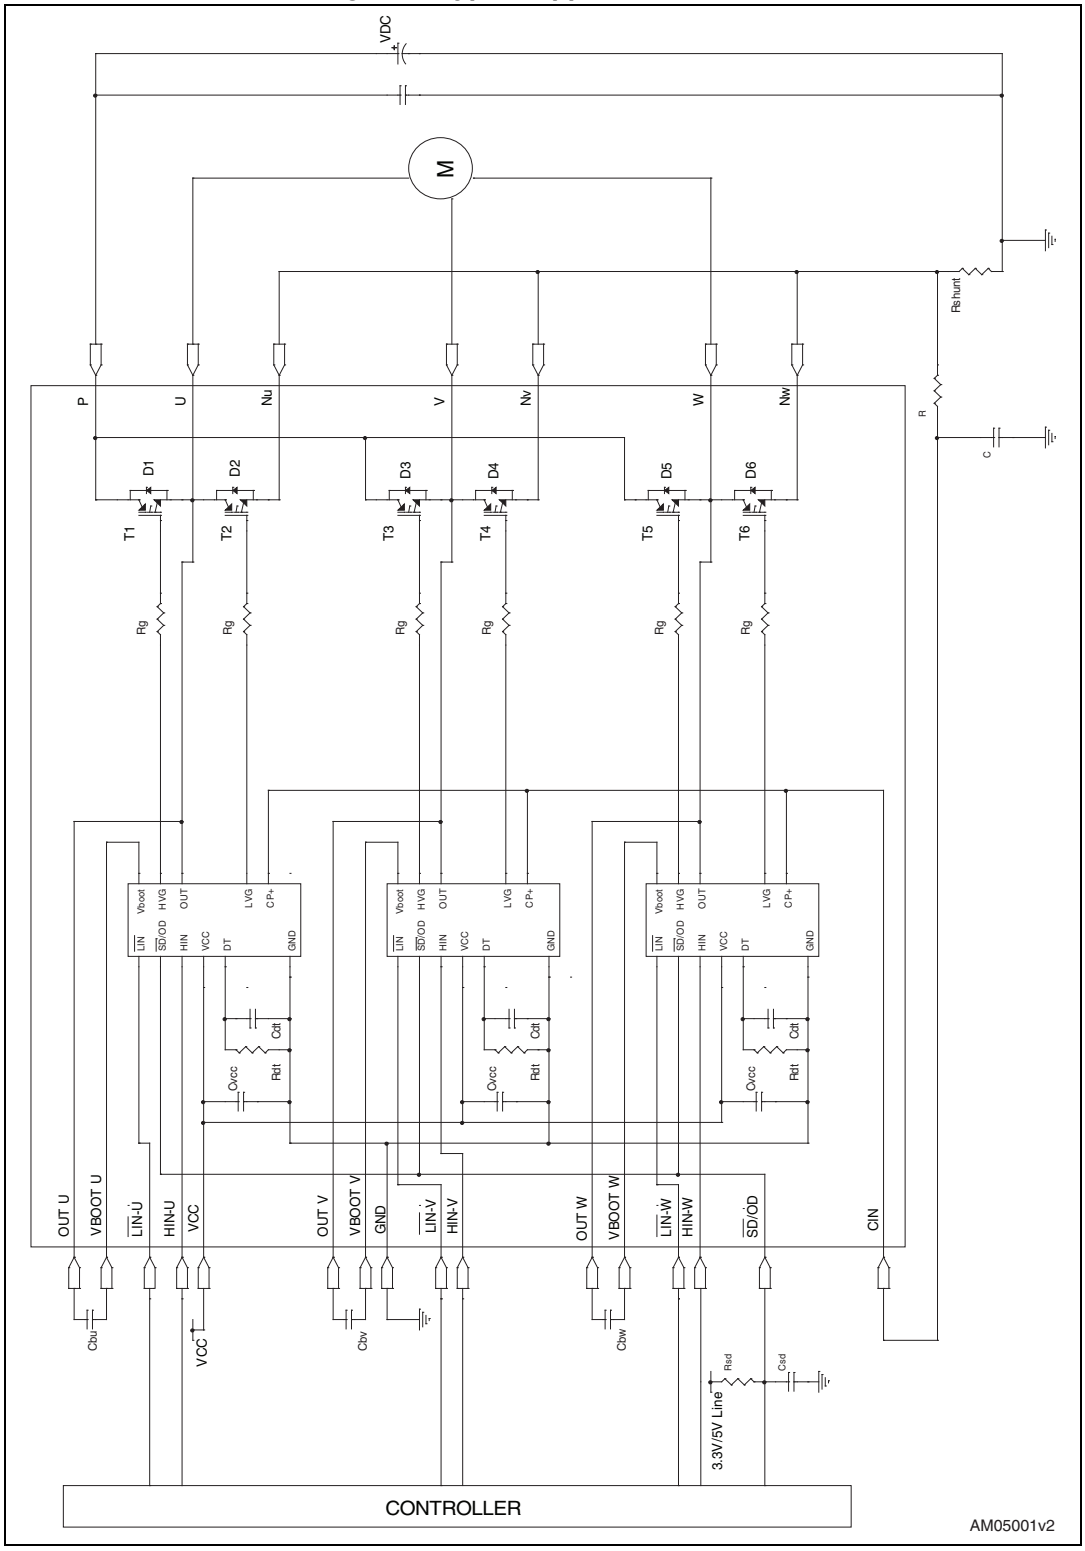
Please refer to *Table 11* for internal propagation delay time details.

5 Application information

Figure 9. Typical application circuit



5.1 Recommendations

- Input signal HIN is active high logic. A 85 kΩ (typ.) pull-down resistor is built-in for each high side input. If an external RC filter is used, for noise immunity, pay attention to the variation of the input signal level.
- Input signal $\overline{\text{LIN}}$ is active low logic. A 720 kΩ (typ.) pull-up resistor, connected to an internal 5 V regulator through a diode, is built-in for each low side input.
- To prevent the input signals oscillation, the wiring of each input should be as short as possible.
- By integrating an application specific type HVIC inside the module, direct coupling to MCU terminals without any opto-coupler is possible.
- Each capacitor should be located as nearby the pins of IPM as possible.
- Low inductance shunt resistors should be used for phase leg current sensing.
- Electrolytic bus capacitors should be mounted as close to the module bus terminals as possible. Additional high frequency ceramic capacitor mounted close to the module pins will further improve performance.
- The $\overline{\text{SD}}$/OD signal should be pulled up to 5 V / 3.3 V with an external resistor (see *Section 4: Smart shutdown function* for detailed info).
