

# Low-Power, Serial, 14-Bit DACs with Voltage Output

## ABSOLUTE MAXIMUM RATINGS

V<sub>DD</sub> to AGND, DGND .....-0.3V to +6.0V  
 AGND to DGND .....-0.3V to +0.3V  
 Digital Inputs to DGND .....-0.3V to +6.0V  
 DOUT, UPO to DGND .....-0.3V to (V<sub>DD</sub> + 0.3V)  
 OUT, REF to AGND .....-0.3V to (V<sub>DD</sub> + 0.3V)  
 OS to AGND .....(AGND - 4.0V) to (V<sub>DD</sub> + 0.3V)  
 Maximum Current into Any Pin.....50mA

Continuous Power Dissipation (T<sub>A</sub> = +70°C)  
 16-Pin QSOP (derate 8mW/°C above +70°C).....667mW  
 Operating Temperature Range .....-40°C to +85°C  
 Storage Temperature Range .....-65°C to +150°C  
 Lead Temperature (soldering, 10s) .....+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS—MAX5170

### MAX5172

## Pin Description

PIN	NAME	FUNCTION
1	OS	Offset Adjustment. Connect to AGND for no offset.
2	OUT	Voltage Output. High impedance when in shutdown. The output voltage is limited to $V_{DD}$ .
3	RS	Reset Mode Select (digital input). Connect to $V_{DD}$ to select midscale reset output voltage. Connect to DGND to select 0 reset output voltage.
4	$\overline{PDL}$	Power-Down Lockout (digital input). Connect to $V_{DD}$ to allow shutdown. Connect to DGND to disable software and hardware shutdown.
5	$\overline{CLR}$	Clear DAC (digital input). Clears the DAC to either zero or midscale as determined by RS.
6	$\overline{CS}$	Chip Select Input (digital input). DIN ignored when $\overline{CS}$ is high.
7	DIN	Serial-Data Input (digital input). Data is clocked in on the rising edge of SCLK.
8	SCLK	Serial Clock Input (digital input)
9	DGND	Digital Ground
10	DOUT	Serial-Data Output
11	UPO	User-Programmable Output. State is set by the serial input.
12	SHDN	Shutdown (digital input). Pulling SHDN high when $\overline{PDL} = V_{DD}$ places the chip in shutdown with a maximum shutdown current of $10\mu A$ .
13	AGND	Analog Ground
14	REF	Reference Input. Maximum $V_{REF}$ is $V_{DD} - 1.4V$ .
15	N.C.	No Connection
16	$V_{DD}$	Positive Supply. Bypass to AGND with a $4.7\mu F$ capacitor in parallel with a $0.1\mu F$ capacitor.

# Low-Power, Serial, 14-Bit DACs with Voltage Output

## Detailed Description

The MAX5170/MAX5172 14-bit, serial, voltage-output DACs operate with a 3-wire serial interface. These devices include a 16-bit shift register and a double-buffered input composed of an input register and a DAC register (see *Functional Diagram*). In addition, these devices employ a rail-to-rail output amplifier and internally trimmed resistors to provide a gain of +1.638V/V, maximizing the output voltage swing. The MAX5170/MAX5172's offset adjust pin allows for a DC shift in the DAC output. The DACs are designed with an inverted R-2R ladder network (Figure 1) which produces a weighted voltage proportional to the reference voltage.

## Reference Inputs

The reference input accepts both AC and DC values with a voltage range extending from 0 to  $V_{DD} - 1.4V$ . The following equation represents the resulting output voltage:

$$V_{OUT} = \frac{V_{REF} \times N \times \text{Gain}}{16384}$$

where N is the numeric value of the DAC's binary input code (0 to 16383),  $V_{REF}$  is the reference voltage, and Gain is the internal set voltage gain (+1.638V/V if OS = AGND). The maximum output voltage is  $V_{DD}$ . The reference pin has a minimum impedance of 18k $\Omega$  and is code dependent.

## Output Amplifier

With OS connected to AGND, the output amplifier employs an internal, trimmed resistor-divider setting the gain to +1.638V/V and minimizing gain error. The output amplifier has a typical slew rate of 0.6V/ $\mu$ s and settles to  $\pm 0.5$ LSB from a full-scale transition within 18 $\mu$ s, when loaded with 5k $\Omega$  in parallel with 100pF. Loads less than 2k $\Omega$  degrade performance.

For alternative output amplifier setups, refer to the *Applications Information* section.

## Shutdown Mode

The MAX5170/MAX5172 feature a software- and hardware-programmable shutdown mode that reduces the typical supply current to 1 $\mu$ A. Enter shutdown by writing the appropriate input-control word as shown in Table 1 or by using the hardware shutdown. In shutdown mode, the reference input and the amplifier output become high-impedance and the serial interface remains active. Data in the input register is saved, allowing the MAX5170/MAX5172 to recall the prior output state when returning to normal operation. Exit shutdown by

Figure 1. Simplified DAC Circuit Diagram

reloading the DAC register from the shift register, by simultaneously loading the input and DAC registers, or by toggling  $\overline{PDL}$ . When returning from shutdown, wait 40 $\mu$ s for the output to settle.

## Power-Down Lockout

Power-Down Lockout disables the software/hardware shutdown mode. A high-to-low transition brings the device out of shutdown and returns the output to its previous state.

## Shutdown

Pulling SHDN high while  $\overline{PDL}$  is high places the MAX5170/MAX5172 in shutdown. Pulling SHDN low will not return the device to normal operation. A high-to-low transition on  $\overline{PDL}$  or an appropriate command from the serial data line (see Table 1 for commands) is required to exit shutdown.

## Serial-Interface

The MAX5170/MAX5172 3-wire serial interface is compatible with SPI, QSPI (Figure 2) and MICROWIRE (Figure 3) interface standards. The 16-bit serial input word consists of two control bits and 14 bits of data (MSB to LSB).

The control bits determine the MAX5170/MAX5172's operation as outlined in Table 1. The MAX5170/MAX5172's digital inputs are double buffered, which allows any of the following:

- Loading the input register without updating the DAC register
- Updating the DAC register from the input register
- Updating the input and DAC registers simultaneously.

# Low-Power, Serial, 14-Bit DACs with Voltage Output

Figure 2. Connections for SPI and QSPI Interface

Figure 3. Connections for MICROWIRE Interface Standards

The MAX5170/MAX5172 accepts one 16-bit packet or two 8-bit packets sent while  $\overline{CS}$  remains low. The MAX5170/MAX5172 allow the following to be configured:

- Clock edge on which serial data output (DOUT) is clocked out
- State of the user-programmable logic output
- Configuration of the reset state.

Specific commands for setting these are shown in Table 1.

The general timing diagram in Figure 4 illustrates how the MAX5170/MAX5172 acquire data.  $\overline{CS}$  must go low at least  $t_{CSS}$  before the rising edge of the serial clock (SCLK). With  $\overline{CS}$  low, data is clocked into the register on the rising edge of SCLK. The maximum serial clock frequency guaranteed for proper operation is 10MHz for MAX5170 and 6MHz for MAX5172. See Figure 5 for a detailed timing diagram of the serial interface.

## Serial Data Output (DOUT)

The serial-data output, DOUT, is the internal shift register's output and allows for daisy-chaining of multiple devices as well as data readback (see *Applications Information*). By default upon start-up, data shifts out of DOUT on the serial clock's rising edge (Mode 0) and provides a lag of 16 clock cycles, thus maintaining SPI, QSPI, and MICROWIRE compatibility. However, if the device is programmed for Mode 1, the output data lags DIN by 16.5 clock cycles and is clocked out on the serial clock's rising edge. During shutdown, DOUT retains its last digital state prior to shutdown.

Table 1. Serial-Interface Programming Commands

16-BIT SERIAL WORD			FUNCTION
C1	C0	D13.....D0	
0	0	14-bit DAC data	Load input register; DAC registers are unchanged.
0	1	14-bit DAC data	Load input register; DAC registers are updated (start-up DAC with new data).
1	0	x x x xxx xxxx xxxx	Update DAC register from input register (start-up DAC with data previously stored in the input registers).
1	1	0 0 x xxx xxxx xxxx	No operation (NOP).
1	1	0 1 x xxx xxxx xxxx	Shut down DAC (provided $\overline{PDL} = 1$ ).
1	1	1 0 0 xxx xxxx xxxx	UPO goes low (default).
1	1	1 0 1 xxx xxxx xxxx	UPO goes high.
1	1	1 1 0 xxx xxxx xxxx	Mode 1, DOUT clocked out on SCLK's rising edge.
1	1	1 1 1 xxx xxxx xxxx	Mode 0, DOUT clocked out on SCLK's falling edge (default).

# Low-Power, Serial, 14-Bit DACs with Voltage Output

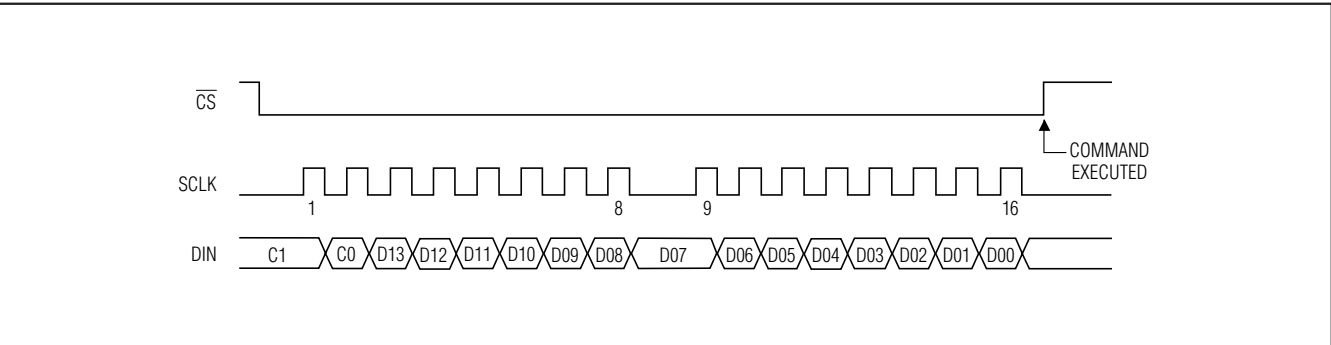

Figure 4. Serial-Interface Timing Diagram

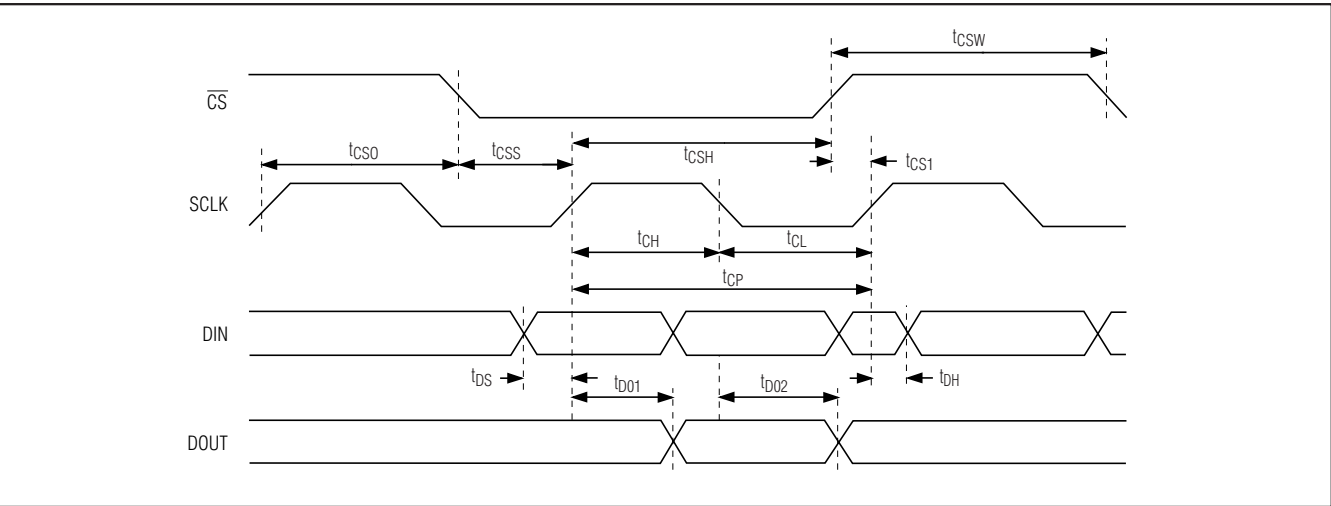

Figure 5. Detailed Serial-Interface Timing Diagram

## User-Programmable Logic Output (UPO)

The UPO allows control of an external device through the serial interface, thereby reducing the number of microcontroller I/O pins required. During power-down, this output retains its digital state prior to shutdown. When  $\overline{\text{CLR}}$  is pulled low, UPO resets to its programmed default state. See Table 1 for specific commands to control the UPO.

## Reset (RS) and Clear ( $\overline{\text{CLR}}$ )

The MAX5170/MAX5172 offers a clear pin which resets the output voltage. If RS = DGND, then  $\overline{\text{CLR}}$  resets the output voltage to the minimum voltage (0 if OS = AGND). If RS = V<sub>DD</sub>, then  $\overline{\text{CLR}}$  resets the output voltage to midscale. In either case,  $\overline{\text{CLR}}$  resets UPO to its programmed default state.

# Low-Power, Serial, 14-Bit DACs with Voltage Output

## Applications Information

### Unipolar Output

Figure 6 shows the MAX5170/MAX5172 configured for unipolar, rail-to-rail operation with a gain of +1.638V/V. Table 2 lists the codes for unipolar output voltages. The maximum output voltage is limited to  $V_{DD}$ . Use the OS pin to introduce an offset voltage as shown in Figure 7 and described in the *Offset and Buffer Configurations* section.

### Bipolar Output

Figure 8 shows the MAX5170/MAX5172 configured for bipolar output operation. The output voltage is given by the following equation (OS = AGND):

$$V_{OUT} = V_{REF} \left( \frac{2 \times N}{16,384} - 1 \right)$$

where N represents the numeric value of the DAC's binary input code,  $V_{REF}$  is the voltage of the external reference. Table 3 shows digital codes and the corresponding output voltage for Figure 8's circuit.

# Low-Power, Serial, 14-Bit DACs with Voltage Output

## Offset and Buffer Configurations

The simple circuit of Figure 7 illustrates how to introduce an offset to the output voltage. The amount of offset introduced by a voltage at the OS pin is shown in the following equation:

$$V_{\text{OFFSET}} = V_{\text{OS}} \times (1 - \text{Gain})$$

where  $\text{Gain} = 1.638$ . However, the total output voltage of the device cannot exceed  $V_{\text{DD}}$  regardless of the voltage on the OS pin.

To set the gain of the output amplifier to 1, connect OS to OUT.

## Daisy-Chaining Devices

The serial data output pin (DOUT) allows multiple MAX5170/MAX5172s to be daisy-chained together, as shown in Figure 9. The advantage of this is that only two lines are needed to control all the DACs on the line. The disadvantage is that it takes  $n$  commands to program the DACs. Figure 10 shows several MAX5170/MAX5172s sharing one common DIN signal line. In this configuration, the data bus is common to all devices. However, more I/O lines are required for this configuration because each device requires a dedicated  $\overline{\text{CS}}$  line. The advantage of this configuration is that only one command is needed to program any DAC.

## Using an AC Reference

The MAX5170/MAX5172 accepts reference voltages with AC components as long as the reference voltage remains between 0 and  $V_{\text{DD}} - 1.4\text{V}$ . Figure 11 shows a technique for applying an offset sine wave signal to REF. The reference voltage must remain above AGND.

## Power-Supply and Layout Considerations

Wire-wrap boards are not recommended. For optimum system performance, use printed circuit boards with separate analog and digital ground planes. Connect the two ground planes together at the low-impedance power-supply source. Connect DGND and AGND pins together at the IC. The best ground connection is achieved by connecting the DAC's DGND and AGND pins together and connecting that point to the system analog ground plane. This is useful because if the DAC's DGND is connected to the system digital ground, digital noise may get through to the DAC's analog portion.

Bypass the power supply with a  $4.7\mu\text{F}$  capacitor in parallel with a  $0.1\mu\text{F}$  capacitor to AGND. Minimize their lead lengths to reduce inductance. If noise becomes an issue, use shielding and/or ferrite beads to increase isolation.

To maintain INL and DNL performance as well as gain drift, it is extremely important to provide the lowest possible reference output impedance at the DAC reference input pin. INL degrades if the series resistance on REF pin exceeds  $0.1\Omega$ . The same consideration must be made for the AGND pin.

## Chip Information

TRANSISTOR COUNT: 3457

[illegible]

The block diagram illustrates the internal architecture of the MAX5170 and MAX5172 DACs. The chip is shown with its various pins and internal functional blocks. The inputs include  $\overline{CS}$ , DIN, SCLK, PDL, SHDN, RS, and  $\overline{CLR}$ . The power pins are VDD, AGND, and DGND. The outputs include DOUT, UPO, OS, and OUT. The internal circuitry includes a SERIAL CONTROL block, a 16-BIT SHIFT REGISTER, a LOGIC OUTPUT block, a DECODE CONTROL block, an INPUT REGISTER, a DAC REGISTER, a DAC, and an op-amp. The op-amp is configured as a voltage follower with a feedback resistor and a resistor to the output. The output is labeled OUT.
