ABSOLUTE MAXIMUM RATINGS

IN, OUT, $\overline{\text{SHDN}}$, $\overline{\text{SKIP}}$ to GND	-0.3V to +6V
PGND to GND	$\pm 0.3\text{V}$
CXN to GND	-0.3V to ($V_{\text{IN}} + 0.3\text{V}$)
CXP to GND	-0.3V to ($V_{\text{OUT}} + 0.3\text{V}$)
Continuous Output Current	
MAX682	300mA
MAX683	150mA
MAX684	75mA
Output Short-Circuit Duration	5sec

Continuous Power Dissipation ($T_A = +70^\circ\text{C}$)	
8-Pin SO (derate 5.9mW/ $^\circ\text{C}$ above $+70^\circ\text{C}$)	471mW
8-Pin μMAX (derate 4.1mW/ $^\circ\text{C}$ above $+70^\circ\text{C}$)	330mW
Operating Temperature Range	
MAX68_E_A	-40°C to $+85^\circ\text{C}$
Junction Temperature	$+150^\circ\text{C}$
Storage Temperature Range	-65°C to $+160^\circ\text{C}$
Lead Temperature (soldering, 10sec)	$+300^\circ\text{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

Pin Description

PIN	NAME	FUNCTION
1	\overline{SKIP}	When $\overline{SKIP} = \text{low}$, the regulator operates in low-quiescent-current skip mode. When $\overline{SKIP} = \text{high}$, the regulator operates in constant-frequency mode, minimizing output ripple and noise. \overline{SKIP} must be tied high for input voltages above 3.6V.
2	\overline{SHDN}	Shutdown Input. Drive \overline{SHDN} through an external resistor. When $\overline{SHDN} = \text{low}$, the device turns off. When current is sourced into \overline{SHDN} through R_{EXT} , the device activates, and the \overline{SHDN} pin input current sets the oscillator's switching frequency. $R_{EXT} (k\Omega) = 45000 (V_{IN} - 0.69V) / f_{OSC} (kHz)$.
3	IN	Input Supply Pin. Can range from 2.7V to 5.5V for $\overline{SKIP} = \text{high}$, and 2.7V to 3.6V for $\overline{SKIP} = \text{low}$. Bypass to PGND with a suitable value capacitor (see <i>Capacitor Selection</i> section).
4	GND	Ground Pin. Connect to PGND through a short trace.
5	PGND	Power Ground Pin
6	CXN	Negative Terminal of the Charge-Pump Transfer Capacitor
7	CXP	Positive Terminal of the Charge-Pump Transfer Capacitor
8	OUT	Fixed 5V Power Output. Bypass to PGND with output filter capacitor.

3.3V-Input to Regulated 5V-Output Charge Pumps

Detailed Description

The MAX682/MAX683/MAX684 charge pumps provide a regulated 5V output from a 2.7V to 5.5V input. They deliver a maximum of 250mA, 100mA, or 50mA load current, respectively. Designed specifically for compact applications, a complete regulator circuit requires only three small external capacitors and one resistor. An externally adjustable switching frequency and innovative control scheme allow the circuit to be optimized for efficiency, size, or output noise. The devices also contain a shutdown feature.

The MAX682/MAX683/MAX684 consist of an error amplifier, a 1.23V bandgap reference, an internal resistive feedback network, an oscillator, high-current MOSFET switches, and shutdown and control logic (Figure 1). Figure 2 shows an idealized unregulated charge-pump voltage doubler. The oscillator runs at a 50% duty cycle. During one half of the period, the transfer capacitor (C_x) charges to the input voltage. During the other half, the doubler stacks the voltage across C_x and the input voltage, and transfers the sum of the two voltages to the output filter capacitor (C_{OUT}). Rather than simply doubling the input voltage, the MAX682/MAX683/MAX684 provide a regulated fixed output voltage (5V) using either skip mode or constant-frequency mode. Skip mode and constant-frequency mode are externally selected via the SKIP input pin.

Figure 1. Functional Block Diagram

Figure 2. Unregulated Voltage Doubler

Figure 3. Skip-Mode Regulation

Skip Mode

In skip mode ($\overline{\text{SKIP}} = \text{low}$), the error amplifier disables switching when it detects an output higher than 5V. The device then skips switching cycles until the output voltage drops. Then the error amplifier reactivates the oscillator. Figure 3 illustrates the regulation scheme. This regulation method minimizes operating current because the device does not switch continuously. SKIP is a logic input and should not remain floating.

Constant-Frequency Mode

When $\overline{\text{SKIP}}$ is high, the charge pump runs continuously at the selected frequency. Figure 4 shows a block diagram of the device in constant-frequency mode. The error amplifier controls the charge on C_x by driving the gate of the N-channel FET. When the output voltage falls, the gate drive increases, resulting in a larger voltage across C_x . This regulation scheme minimizes output ripple. Since the device switches continuously, the

3.3V-Input to Regulated 5V-Output Charge Pumps

Figure 4. Constant-Frequency-Mode Regulation

Table 1. Tradeoffs Between Operating Modes

FEATURE	SKIP MODE (SKIP = LOW)	CONSTANT-FREQUENCY MODE (SKIP = HIGH)
Best Light-Load Efficiency	✓	
Smallest External Component Size		✓
Output Ripple Amplitude and Frequency	Relatively large amplitude, variable frequency	Relatively small amplitude, constant frequency
Load Regulation	Very Good	Good

output noise contains well-defined frequency components, and the circuit requires much smaller external capacitors for a given output ripple. However, constant-frequency mode, due to higher operating current, is less efficient at light loads than skip mode. Note: For input voltages above 3.6V, the devices must operate in constant-frequency mode. Table 1 summarizes the tradeoffs between the two operating modes.

Frequency Selection and Shutdown

The $\overline{\text{SHDN}}$ pin on the MAX682/MAX683/MAX684 performs a dual function: it shuts down the device and determines the oscillator frequency. The $\overline{\text{SHDN}}$ input looks like a diode to ground and should be driven through a resistor.

Driving $\overline{\text{SHDN}}$ low places the device in shutdown mode. This disables all switches, the oscillator, and control logic. The device typically draws 0.1 μA (5 μA

max) of supply current in this mode and the output presents a 50k Ω impedance to ground. The device exits shutdown once $\overline{\text{SHDN}}$ is forward biased (minimum of 1 μA of current). The typical no-load shutdown exit time is 50 μs .

When $\overline{\text{SHDN}}$ is pulled high through an external resistor to V_{IN} , the bias current into $\overline{\text{SHDN}}$ determines the charge-pump frequency. To select the frequency, calculate the external resistor value, R_{EXT} , using the following formula:

$$R_{\text{EXT}} = 45000 (V_{\text{IN}} - 0.69\text{V}) / f_{\text{OSC}}$$

where R_{EXT} is in k Ω and f_{OSC} is in kHz. Program the frequency in the 50kHz to 2MHz range. This frequency range corresponds to $\overline{\text{SHDN}}$ input currents between 1 μA and 50 μA . Proper operation of the oscillator is not guaranteed beyond these limits. Currents lower than 1 μA may shut down the device. The forward-biased diode voltage from the $\overline{\text{SHDN}}$ input to GND has a temperature coefficient of -2mV/ $^{\circ}\text{C}$.

Undervoltage Lockout

The MAX682/MAX683/MAX684 have an undervoltage-lockout feature that deactivates the devices when the input voltage falls below 2.25V. Regulation at low input voltages cannot be maintained. This safety feature ensures that the device shuts down before the output voltage falls out of regulation by a considerable amount (typically 10% with no load). Once deactivated, hysteresis holds the device in shutdown until the input voltage rises 100mV above the lockout threshold.

Applications Information

Capacitor Selection

The MAX682/MAX683/MAX684 require only three external capacitors (Figure 5). Their values are closely linked to the output current capacity, oscillator frequency, output noise content, and mode of operation.

Generally, the transfer capacitor (C_X) will be the smallest, and the input capacitor (C_{IN}) is twice as large as C_X . Higher switching frequencies allow the use of smaller C_X and C_{IN} . The output capacitor (C_{OUT}) can be anywhere from 5-times to 50-times larger than C_X , depending on the mode of operation and ripple tolerance. In continuous switching mode, smaller output ripple allows smaller C_{OUT} . In skip mode, a larger C_{OUT} is required to maintain low output ripple. Tables 2 and 3 show capacitor values recommended for lowest supply-current operation (skip mode) and smallest size operation (constant-frequency mode), respectively.

3.3V-Input to Regulated 5V-Output Charge Pumps

Table 2. Recommended Capacitor Values for Quiescent Current (Skip Mode)

PART	OUTPUT (mA)	C _{IN} (μF)	C _X (μF)	C _{OUT} (μF)		V _{OUT} RIPPLE (mV)
				TANTALUM	CERAMIC	
MAX682	250	2.2	1	47	10	100
MAX683	100	1	0.47	22	4.7	100
MAX684	50	0.47	0.22	10	2.2	100

Table 3. Recommended Capacitor Values for Smallest Size (Constant-Frequency Mode, I_{SHDN} = 22μA, 1MHz)

PART	OUTPUT (mA)	C _{IN} (μF)	C _X (μF)	CERAMIC C _{OUT} (μF)	V _{OUT} RIPPLE (mV)
MAX682	250	1	0.47	2.2	80
MAX683	100	0.47	0.22	1	80
MAX684	50	0.22	0.1	0.47	80

Table 4. Recommended Capacitor Manufacturers

VALUE	DESCRIPTION	MANUFACTURER	PHONE NUMBER
47μF to 10μF	595D-series tantalum surface mount	Sprague	(603) 224-1961
47μF to 10μF	TPS-series surface mount	AVX	(803) 946-0690
0.1μF to 2.2μF	Ceramic surface mount	TDK	(847) 390-4373

In addition, the following two equations approximate output ripple for each mode. In skip mode, output ripple is dominated by ESR, and is approximately:

$$V_{\text{RIPPLE}}(\text{SKIP}) \approx (2V_{\text{IN}} - V_{\text{OUT}}) \text{ESR}_{\text{COUT}} / R_{\text{TX}}$$

Figure 5. Standard Operating Circuit

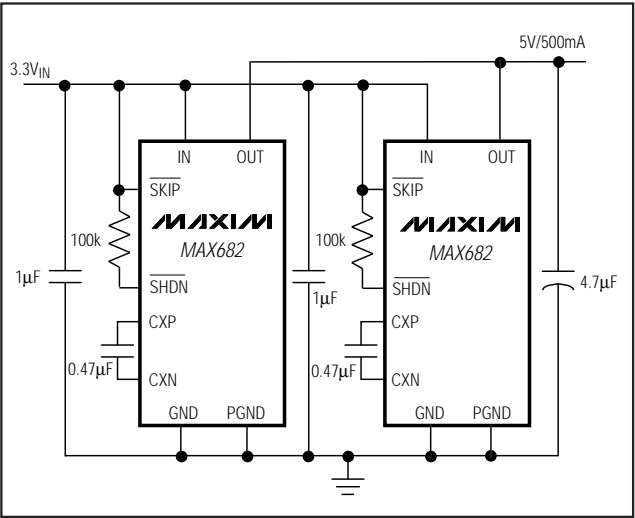

Figure 6. Paralleling Two MAX682s

where ESR_{COUT} is the ESR of the output filter capacitance, and R_{TX} is the open-loop output transfer resistance of the IC. R_{TX} is typically 0.8Ω for the MAX682, 1.6Ω for the MAX683, and 3Ω for the MAX684. In constant-frequency mode, output ripple is dominated by COUT and is approximately:

$$V_{\text{RIPPLE}}(\text{const-freq}) \approx I_{\text{OUT}} / (2 \times f_{\text{OSC}} \times \text{COUT})$$

All capacitors must maintain a low ($<100\text{m}\Omega$) equivalent series resistance (ESR). Table 4 lists the manufacturers of recommended capacitors. Surface-mount tantalum capacitors will work well for most applications. Ceramic capacitors will provide the lowest ripple due to their typically lower ESR.

If the source impedance or inductance of the input supply is large, additional input bypassing ($2.2\mu\text{F}$ to $22\mu\text{F}$) may be needed. This additional capacitance need not be a low-ESR type.

3.3V-Input to Regulated 5V-Output Charge Pumps

Power Dissipation

The power dissipated in the MAX682/MAX683/MAX684 depends on output current and is accurately described by:

$$P_{DISS} = I_{OUT} (2V_{IN} - V_{OUT})$$

P_{DISS} must be less than that allowed by the package rating. See the *Absolute Maximum Ratings* for 8-pin μ MAX (MAX683/MAX684) and SO (MAX682) power-dissipation limits and deratings.

Layout Considerations

All capacitors should be soldered in close proximity to the IC. Connect ground and power ground through a short, low-impedance trace. If a high-value resistor is driving the shutdown input and is picking up noise (i.e., frequency jitter at CXP and CXN), bypass \overline{SHDN} to GND with a small capacitor (0.01 μ F).

Paralleling Devices

The MAX682/MAX683/MAX684 can be paralleled to yield higher load currents. The circuit of Figure 6 can deliver 500mA at 5V. It uses two MAX682s in parallel. The devices can share the output capacitors, but each one requires its own transfer capacitor (C_X) and input capacitor. For best performance, the paralleled devices should operate in the same mode (skip or constant frequency).
