## REVISION HISTORY

6/06—Revision 0: Initial Version

## SPECIFICATIONS

$V_{DD} = +2.7\text{ V to }+5.5\text{ V}$ ;  $R_L = 2\text{ k}\Omega$  to GND;  $C_L = 200\text{ pF}$  to GND;  $V_{REF} = V_{DD}$ ; all specifications  $T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.

Output Noise Spectral Density		120		$\text{nV}/\sqrt{\text{Hz}}$	DAC code = midscale, 1 kHz
		100		$\text{nV}/\sqrt{\text{Hz}}$	DAC code = midscale, 10 kHz
Output Noise		15		$\mu\text{V p-p}$	0.1 Hz to 10 Hz

<sup>1</sup> Guaranteed by design and characterization, not production tested.

<sup>2</sup> Temperature range:  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$ ; typical at  $25^{\circ}\text{C}$ .

<sup>3</sup> See the Terminology section.

## TIMING CHARACTERISTICS

All input signals are specified with  $t_R = t_F = 1 \text{ ns/V}$  (10% to 90% of  $V_{DD}$ ) and timed from a voltage level of  $(V_{IL} + V_{IH})/2$  (see Figure 2).  $V_{DD} = 2.7 \text{ V}$  to  $5.5 \text{ V}$ ; all specifications  $T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.

Table 4.

Parameter <sup>1</sup>	Limit at $T_{MIN}, T_{MAX}$ $V_{DD} = 2.7 \text{ V to } 5.5 \text{ V}$	Unit	Conditions/Comments
$t_1^2$	20	ns min	SCLK cycle time
$t_2$	9	ns min	SCLK high time
$t_3$	9	ns min	SCLK low time
$t_4$	13	ns min	$\overline{\text{SYNC}}$ to SCLK falling edge setup time
$t_5$	5	ns min	Data setup time
$t_6$	5	ns min	Data hold time
$t_7$	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge
$t_8$	15	ns min	Minimum $\overline{\text{SYNC}}$ high time
$t_9$	13	ns min	$\overline{\text{SYNC}}$ rising edge to SCLK fall ignore
$t_{10}$	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ fall ignore

<sup>1</sup> Guaranteed by design and characterization, not production tested.

<sup>2</sup> Maximum SCLK frequency is 50 MHz at  $V_{DD} = 2.7 \text{ V to } 5.5 \text{ V}$ .

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

Table 5.

Parameter	Rating
$V_{DD}$ to GND	$-0.3\text{ V to }+7\text{ V}$
$V_{OUT}$ to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
$V_{REF}$ to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
Digital Input Voltage to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
Operating Temperature Range	
Industrial (A Grade, B Grade)	$-40^\circ\text{C to }+105^\circ\text{C}$
Storage Temperature Range	$-65^\circ\text{C to }+150^\circ\text{C}$
Junction Temperature ( $T_J$ max)	$150^\circ\text{C}$
Power Dissipation	$(T_J \text{ max} - T_A)/\theta_{JA}$
LFCSP_WD Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	$61^\circ\text{C/W}$
MSOP Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	$142^\circ\text{C/W}$
$\theta_{JC}$ Thermal Impedance	$43.7^\circ\text{C/W}$
Reflow Soldering Peak Temperature	
Pb-Free	$260^\circ\text{C} \pm 5^\circ\text{C}$

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 3. Pin Configuration

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	V <sub>OUTA</sub>	Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
2	V <sub>OUTB</sub>	Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
3	GND	Ground Reference Point for All Circuitry on the Part.
4	V <sub>OUTC</sub>	Analog Output Voltage from DAC C. The output amplifier has rail-to-rail operation.
5	V <sub>OUTD</sub>	Analog Output Voltage from DAC D. The output amplifier has rail-to-rail operation.
6	$\overline{\text{SYNC}}$	Active Low Control Input. This is the frame synchronization signal for the input data. When $\overline{\text{SYNC}}$ goes low, it powers on the SCLK and DIN buffers and enables the input shift register. Data is transferred in on the falling edges of the next 24 clocks. If $\overline{\text{SYNC}}$ is taken high before the 24 <sup>th</sup> falling edge, the rising edge of $\overline{\text{SYNC}}$ acts as an interrupt and the write sequence is ignored by the device.
7	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates up to 50 MHz.
8	DIN	Serial Data Input. This device has a 24-bit input shift register. Data is clocked into the register on the falling edge of the serial clock input.
9	V <sub>DD</sub>	Power Supply Input. These parts can be operated from 2.7 V to 5.5 V. The supply should be decoupled with a 10 $\mu\text{F}$ capacitor in parallel with a 0.1 $\mu\text{F}$ capacitor to GND.
10	V <sub>REF</sub>	Reference Voltage Input.

## TERMINOLOGY

### Relative Accuracy or Integral Nonlinearity (INL)

For the DAC, relative accuracy or integral nonlinearity is a measurement of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function. A typical INL vs. code plot can be seen in Figure 4 and Figure 5.

### Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of  $\pm 1$  LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. A typical DNL vs. code plot can be seen in Figure 6 and Figure 7.

### Zero-Scale Error

Zero-scale error is a measurement of the output error when zero code (0x0000) is loaded to the DAC register. Ideally, the output should be 0 V. The zero-code error is always positive in the AD5624/AD5664 because the output of the DAC cannot go below 0 V. It is due to a combination of the offset errors in the DAC and the output amplifier. Zero-code error is expressed in mV. A plot of zero-code error vs. temperature can be seen in Figure 12.

### Full-Scale Error

Full-scale error is a measurement of the output error when full-scale code (0xFFFF) is loaded to the DAC register. Ideally, the output should be  $V_{DD} - 1$  LSB. Full-scale error is expressed in % of FSR. A plot of full-scale error vs. temperature can be seen in Figure 11.

### Gain Error

This is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from ideal expressed as a % of FSR.

### Zero-Code Error Drift

This is a measurement of the change in zero-code error with a change in temperature. It is expressed in  $\mu\text{V}/^\circ\text{C}$ .

### Gain Temperature Coefficient

This is a measurement of the change in gain error with changes in temperature. It is expressed in ppm of FSR/ $^\circ\text{C}$ .

### Offset Error

Offset error is a measure of the difference between  $V_{\text{OUT}}$  (actual) and  $V_{\text{OUT}}$  (ideal) expressed in mV in the linear region of the transfer function. Offset error is measured on the AD5624/AD5664 with code 512 loaded in the DAC register. It can be negative or positive.

### DC Power Supply Rejection Ratio (PSRR)

This indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in  $V_{\text{OUT}}$  to a change in  $V_{\text{DD}}$  for full-scale output of the DAC. It is measured in dB.  $V_{\text{REF}}$  is held at 2 V, and  $V_{\text{DD}}$  is varied by  $\pm 10\%$ .

### Output Voltage Settling Time

This is the amount of time it takes for the output of a DAC to settle to a specified level for a  $\frac{1}{4}$  to  $\frac{3}{4}$  full-scale input change and is measured from the 24<sup>th</sup> falling edge of SCLK.

### Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-s, and is measured when the digital input code is changed by 1 LSB at the major carry transition (0x7FFF to 0x8000) as shown in Figure 22.

### Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC, but is measured when the DAC output is not updated. It is specified in nV-s, and measured with a full-scale code change on the data bus, that is, from all 0s to all 1s and vice versa.

### Total Harmonic Distortion (THD)

This is the difference between an ideal sine wave and its attenuated version using the DAC. The sine wave is used as the reference for the DAC, and the THD is a measurement of the harmonics present on the DAC output. It is measured in dB.

### Noise Spectral Density

This is a measurement of the internally generated random noise. Random noise is characterized as a spectral density ( $\text{nV}/\sqrt{\text{Hz}}$ ). It is measured by loading the DAC to midscale and measuring noise at the output. It is measured in  $\text{nV}/\sqrt{\text{Hz}}$ . A plot of noise spectral density can be seen in Figure 27.

### DC Crosstalk

DC crosstalk is the dc change in the output level of one DAC in response to a change in the output of another DAC. It is measured with a full-scale output change on one DAC (or soft power-down and power-up) while monitoring another DAC kept at midscale. It is expressed in  $\mu\text{V}$ .

DC crosstalk due to load current change is a measure of the impact that a change in load current on one DAC has to another DAC kept at midscale. It is expressed in  $\mu\text{V}/\text{mA}$ .

### Digital Crosstalk

This is the glitch impulse transferred to the output of one DAC at midscale in response to a full-scale code change (all 0s to all 1s and vice versa) in the input register of another DAC. It is measured in standalone mode and is expressed in nV-s.

### Analog Crosstalk

This is the glitch impulse transferred to the output of one DAC due to a change in the output of another DAC. It is measured by loading one of the input registers with a full-scale code change (all 0s to all 1s and vice versa). Then execute a software LDAC and monitor the output of the DAC whose digital code was not changed. The area of the glitch is expressed in nV-s (see Figure 23).

### DAC-to-DAC Crosstalk

This is the glitch impulse transferred to the output of one DAC due to a digital code change and subsequent analog output change of another DAC. It is measured by loading the attack channel with a full-scale code change (all 0s to all 1s and vice versa) using the command write to and update while monitoring the output of the victim channel that is at midscale. The energy of the glitch is expressed in nV-s.

### Multiplying Bandwidth

The amplifiers within the DAC have a finite bandwidth. The multiplying bandwidth is a measure of this. A sine wave on the reference (with full-scale code loaded to the DAC) appears on the output. The multiplying bandwidth is the frequency at which the output amplitude falls to 3 dB below the input.

## THEORY OF OPERATION

### D/A SECTION

The AD5624/AD5664 DACs are fabricated on a CMOS process. The architecture consists of a string DAC followed by an output buffer amplifier. Figure 29 shows a block diagram of the DAC architecture.

Figure 29. DAC Architecture

Since the input coding to the DAC is straight binary, the ideal output voltage is given by

$$V_{OUT} = V_{REFIN} \times \left( \frac{D}{2^N} \right)$$

where:

$D$  is the decimal equivalent of the binary code that is loaded to the DAC register:

0 to 4095 for AD5624 (12 bit).

0 to 65535 for AD5664 (16 bit).

$N$  is the DAC resolution.

### RESISTOR STRING

The resistor string is shown in Figure 30. It is simply a string of resistors, each of value  $R$ . The code loaded to the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic.

### OUTPUT AMPLIFIER

The output buffer amplifier can generate rail-to-rail voltages on its output, which gives an output range of 0 V to  $V_{DD}$ . It can drive a load of 2 k $\Omega$  in parallel with 1000 pF to GND. The source and sink capabilities of the output amplifier can be seen in Figure 17. The slew rate is 1.8 V/ $\mu$ s with a  $\frac{1}{4}$  to  $\frac{3}{4}$  full-scale settling time of 7  $\mu$ s.

Figure 30. Resistor String

### SERIAL INTERFACE

The AD5624/AD5664 have a 3-wire serial interface ( $\overline{\text{SYNC}}$ , SCLK, and DIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards as well as with most DSPs. See Figure 2 for a timing diagram of a typical write sequence.

The write sequence begins by bringing the  $\overline{\text{SYNC}}$  line low. Data from the DIN line is clocked into the 24-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high as 50 MHz, making the AD5624/AD5664 compatible with high speed DSPs. On the 24<sup>th</sup> falling clock edge, the last data bit is clocked in and the programmed function is executed, that is, a change in DAC register contents and/or a change in the mode of operation. At this stage, the  $\overline{\text{SYNC}}$  line can be kept low or be brought high. In either case, it must be brought high for a minimum of 15 ns before the next write sequence so that a falling edge of  $\overline{\text{SYNC}}$  can initiate the next write sequence. Since the  $\overline{\text{SYNC}}$  buffer draws more current when  $V_{IN} = 2.0$  V than it does when  $V_{IN} = 0.8$  V,  $\overline{\text{SYNC}}$  should be idled low between write sequences for even lower power operation. It must, however, be brought high again just before the next write sequence.

# AD5624/AD5664

## INPUT SHIFT REGISTER

The input shift register is 24 bits wide. The first two bits are don't care bits. The next three bits are the Command bits, C2 to C0 (see Table 7), followed by the 3-bit DAC address, A2 to A0 (see Table 8), and then the 16-, 12-bit data-word. The data-word comprises the 16-, 12-bit input code followed by 0 or 4 don't care bits for the AD5664 and AD5624 respectively (see Figure 31 and Figure 32). These data bits are transferred to the DAC register on the 24<sup>th</sup> falling edge of SCLK.

Table 7. Command Definition

C2	C1	C0	Command
0	0	0	Write to input register <i>n</i>
0	0	1	Update DAC register <i>n</i>
0	1	0	Write to input register <i>n</i> , update all (software LDAC)
0	1	1	Write to and update DAC channel <i>n</i>
1	0	0	Power down DAC (power-up)
1	0	1	Reset
1	1	0	Load LDAC register
1	1	1	Reserved

Table 8. Address Command

A2	A1	A0	ADDRESS ( <i>n</i> )
0	0	0	DAC A
0	0	1	DAC B
0	1	0	DAC C
0	1	1	DAC D
1	1	1	All DACs

## SYNC INTERRUPT

In a normal write sequence, the  $\overline{\text{SYNC}}$  line is kept low for at least 24 falling edges of SCLK, and the DAC is updated on the 24<sup>th</sup> falling edge. However, if  $\overline{\text{SYNC}}$  is brought high before the 24<sup>th</sup> falling edge, then this acts as an interrupt to the write sequence. The input shift register is reset and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs (see Figure 33).

## POWER-ON RESET

The AD5624/AD5664 family contains a power-on reset circuit that controls the output voltage during power-up. The AD5624/AD5664 DAC outputs power up to 0 V and the output remains there until a valid write sequence is made to the DAC. This is useful in applications where it is important to know the state of the output of the DAC while it is in the process of powering up.

Figure 31. AD5664 Input Shift Register Contents

Figure 32. AD5624 Input Shift Register Contents

Figure 33.  $\overline{\text{SYNC}}$  Interrupt Facility

## SOFTWARE RESET

The AD5624/AD5664 contain a software reset function. Command 110 is reserved for the software reset function (see Table 7). The software reset command contains two reset modes that are software programmable by setting Bit DB0 in the control register. Table 9 shows how the state of the bit corresponds to the software reset modes of operation of the devices.

**Table 9. Software Reset Modes for the AD5624/AD5664**

DB0	Registers Reset to Zero
0	DAC register Input shift register
1 (Power-On Reset)	DAC register Input shift register LDAC register Power-down register

## POWER-DOWN MODES

The AD5624/AD5664 contain four separate modes of operation. Command 100 is reserved for the power-down function (see Table 7). These modes are software programmable by setting two bits (DB5 and DB4) in the control register. Table 10 shows how the state of the bits corresponds to the mode of operation of the device. All DACs (DAC D to DAC A) can be powered down to the selected mode by setting the corresponding four bits (DB3, DB2, DB1, and DB0) to 1. By executing the same Command 100, any combination of DACs is powered up by setting Bit DB5 and Bit DB4 to normal operation mode. To select which combination of DAC channels to power-up, set the corresponding four bits (DB3, DB2, DB1, and DB0) to 1. See Table 11 for contents of the input shift register during the power-down/power-up operation.

**Table 10. Modes of Operation for the AD5624/AD5664**

DB5	DB4	Operating Mode
0	0	Normal operation Power-down modes
0	1	1 kΩ to GND
1	0	100 kΩ to GND
1	1	Three-state

When both bits are set to 0, the parts work normally with their normal power consumption of 450  $\mu$ A at 5 V. However, for the three power-down modes, the supply current falls to 480 nA at 5 V (200 nA at 3 V). Not only does the supply current fall, but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This allows the output impedance of the part to be known while the part is in power-down mode.

The outputs can either be connected internally to GND through a 1 kΩ or 100 kΩ resistor, or left open-circuited (three-state) (see Figure 34).

*Figure 34. Output Stage During Power-Down*

The bias generator, the output amplifier, the resistor string, and other associated linear circuitry are shut down when power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 4  $\mu$ s for  $V_{DD} = 5$  V and for  $V_{DD} = 3$  V (see Figure 21).

**Table 11. 24-Bit Input Shift Register Contents of Power-Down/Power-Up Operation**

## LDAC FUNCTION

The AD5624/AD5664 DACs have double-buffered interfaces consisting of two banks of registers: input registers and DAC registers. The input registers are connected directly to the input shift register and the digital code is transferred to the relevant input register on completion of a valid write sequence. The DAC registers contain the digital code used by the resistor strings.

The double-buffered interface is useful if the user requires simultaneous updating of all DAC outputs. The user can write to three of the input registers individually and then write to the remaining input register and update all DAC registers, the outputs update simultaneously. Command 010 is reserved for this software LDAC.

Access to the DAC registers is controlled by the LDAC function. The LDAC registers contain two modes of operation for each DAC channel. The DAC channels are selected by setting the bits of the 4-bit LDAC register (DB3, DB2, DB1, and DB0). Command 110 is reserved for setting up the LDAC register. When the LDAC bit register is set low, the corresponding DAC registers are latched and the input registers can change state without affecting the contents of the

DAC registers. When the LDAC bit register is set high, however, the DAC registers become transparent and the contents of the input registers are transferred to them on the falling edge of the 24<sup>th</sup> SCLK pulse. This is equivalent to having an LDAC hardware pin tied permanently low for the selected DAC channel, that is, synchronous update mode. See Table 12 for the LDAC register mode of operation. See Table 13 for contents of the input shift register during the LDAC register set-up command.

This flexibility is useful in applications where the user wants to update select channels simultaneously, while the rest of the channels update synchronously.

**Table 12. LDAC Register Mode of Operation**

Load DAC Register	
LDAC Bits (DB3 to DB0)	LDAC Mode of Operation
0	Normal operation (default), DAC register update is controlled by write command.
1	The DAC registers are updated after new data is read in on the falling edge of the 24 <sup>th</sup> SCLK pulse.

**Table 13. 24-Bit Input Shift Register Contents for LDAC Setup Command for the AD5624/AD5664**

DB23 to DB22 (MSB)	DB21	DB20	DB19	DB18	DB17	DB16	DB15 to DB4	DB3	DB2	DB1	DB0 (LSB)
x	1	1	0	x	x	x	x	DacD	DacC	DacB	DacA
Don't Care	Command bits (C2 to C0)			Address bits (A3 to A0); don't care			Don't cares	Set bit to 0 or 1 for required mode of operation on respective channel			

## MICROPROCESSOR INTERFACING

### AD5624/AD5664 to Blackfin® ADSP-BF53x Interface

Figure 35 shows a serial interface between the AD5624/AD5664 and the Blackfin ADSP-BF53x microprocessor. The ADSP-BF53x processor family incorporates two dual-channel synchronous serial ports, SPORT1 and SPORT0, for serial and multiprocessor communications. Using SPORT0 to connect to the AD5624/AD5664, the setup for the interface is as follows. DTOPRI drives the DIN pin of the AD5624/AD5664, while TSCLK0 drives the SCLK of the part. The SYNC is driven from TFS0.

Figure 35. Blackfin ADSP-BF53x Interface to AD5624/AD5664

### AD5624/AD5664 to 68HC11/68L11 Interface

Figure 36 shows a serial interface between the AD5624/AD5664 and the 68HC11/68L11 microcontroller. SCK of the 68HC11/68L11 drives the SCLK of the AD5624/AD5664, while the MOSI output drives the serial data line of the DAC. The SYNC signal is derived from a port line (PC7).

The SYNC signal is derived from a port line (PC7). The setup conditions for correct operation of this interface are as follows. The 68HC11/68L11 is configured with its CPOL bit as a 0 and its CPHA bit as a 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured as described previously, data appearing on the MOSI output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 10-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. To load data to the AD5624/AD5664, PC7 is left low after the first eight bits are transferred, and a second serial write operation is performed to the DAC; PC7 is taken high at the end of this procedure.

Figure 36. 68HC11/68L11 Interface to AD5624/AD5664

### AD5624/AD5664 to 80C51/80L51 Interface

Figure 37 shows a serial interface between the AD5624/AD5664 and the 80C51/80L51 microcontroller. The setup for the interface is as follows. TxD of the 80C51/80L51 drives SCLK of the AD5624/AD5664, while RxD drives the serial data line of the part. The SYNC signal is derived from a bit-programmable pin on the port. In this case, port line P3.3 is used. When data is transmitted to the AD5624/AD5664, P3.3 is taken low. The 80C51/80L51 transmits data in 10-bit bytes only; thus only eight falling clock edges occur in the transmit cycle. To load data to the DAC, P3.3 is left low after the first eight bits are transmitted, and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken high following the completion of this cycle. The 80C51/80L51 output the serial data in a format that has the LSB first. The AD5624/AD5664 must receive data with the MSB first. The 80C51/80L51 transmit routine should take this into account.

Figure 37. 80C51/80L51 Interface to AD5624/AD5664

### AD5624/AD5664 to MICROWIRE Interface

Figure 38 shows an interface between the AD5624/AD5664 and any MICROWIRE-compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the AD5624/AD5664 on the rising edge of the SK.

Figure 38. MICROWIRE Interface to AD5624/AD5664

## APPLICATIONS

### CHOOSING A REFERENCE FOR THE AD5624/AD5664

To achieve the optimum performance from the AD5624/AD5664, thought should be given to the choice of a precision voltage reference. The AD5624/AD5664 have only one reference input,  $V_{REF}$ . The voltage on the reference input is used to supply the positive input to the DAC. Therefore, any error in the reference is reflected in the DAC.

When choosing a voltage reference for high accuracy applications, the sources of error are initial accuracy, ppm drift, long-term drift, and output voltage noise. Initial accuracy on the output voltage of the DAC leads to a full-scale error in the DAC. To minimize these errors, a reference with high initial accuracy is preferred. Choosing a reference with an output trim adjustment, such as the [ADR423](#), allows a system designer to trim out system errors by setting a reference voltage to a voltage other than the nominal. The trim adjustment can also be used at temperature to trim out any error.

Long-term drift is a measurement of how much the reference drifts over time. A reference with a tight long-term drift specification ensures that the overall solution remains relatively stable during its entire lifetime.

The temperature coefficient of a reference's output voltage affects INL, DNL, and TUE. A reference with a tight temperature coefficient specification should be chosen to reduce temperature dependence of the DAC output voltage in ambient conditions.

In high accuracy applications, which have a relatively low noise budget, reference output voltage noise needs to be considered. It is important to choose a reference with as low an output noise voltage as practical for the system noise resolution required. Precision voltage references such as the [ADR425](#) produce low output noise in the 0.1 Hz to 10 Hz range. Examples of recommended precision references for use as supply to the AD5624/AD5664 are shown in the Table 14.

### USING A REFERENCE AS A POWER SUPPLY FOR THE AD5624/AD5664

Because the supply current required by the AD5624/AD5664 is extremely low, an alternative option is to use a voltage reference to supply the required voltage to the part (see Figure 39). This is especially useful if the power supply is quite noisy, or if the system supply voltages are at some value other than 5 V or 3 V, for example, 15 V. The voltage reference outputs a steady supply voltage for the AD5624/AD5664 (see Table 14 for a suitable reference). If the low dropout [REF195](#) is used, it must supply 450  $\mu$ A of current to the AD5624/AD5664, with no load on the output of the DAC. When the DAC output is loaded, the [REF195](#) also needs to supply the current to the load. The total current required (with a 5 k $\Omega$  load on the DAC output) is

$$450 \mu\text{A} + (5 \text{ V} / 5 \text{ k}\Omega) = 1.45 \text{ mA}$$

The load regulation of the [REF195](#) is typically 2 ppm/mA, which results in a 2.9 ppm (14.5  $\mu$ V) error for the 1.45 mA current drawn from it. This corresponds to a 0.191 LSB error.

Figure 39. REF195 as Power Supply to the AD5624/AD5664

Table 14. Partial List of Precision References for Use with the AD5624/AD5664

Part No.	Initial Accuracy (mV max)	Temp Drift (ppm/°C max)	0.1 Hz to 10 Hz Noise ( $\mu$ V p-p typ)	V <sub>OUT</sub> (V)
<a href="#">ADR425</a>	$\pm 2$	3	3.4	5
<a href="#">ADR395</a>	$\pm 6$	25	5	5
<a href="#">REF195</a>	$\pm 2$	5	50	5

<a href="#">ADR423</a>	$\pm 2$	3	3.4	3

## BIPOLAR OPERATION USING THE AD5624/AD5664

The AD5624/AD5664 have been designed for single-supply operation, but a bipolar output range is also possible using the circuit in Figure 40. The circuit gives an output voltage range of  $\pm 5$  V. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

The output voltage for any input code can be calculated as follows:

$$V_O = \left[ V_{DD} \times \left( \frac{D}{65,536} \right) \times \left( \frac{R1 + R2}{R1} \right) - V_{DD} \times \left( \frac{R2}{R1} \right) \right]$$

where  $D$  represents the input code in decimal (0 to 65536).  
With  $V_{DD} = 5$  V,  $R1 = R2 = 10$  k $\Omega$ ,

$$V_O = \left( \frac{10 \times D}{65,536} \right) - 5 \text{ V}$$

This is an output voltage range of  $\pm 5$  V, with 0x0000 corresponding to a  $-5$  V output, and 0xFFFF corresponding to a  $+5$  V output.

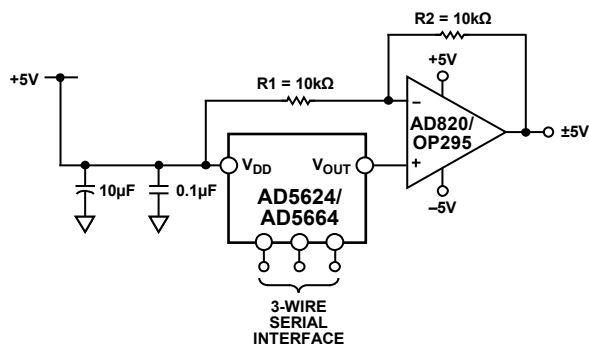

Figure 40. Bipolar Operation with the AD5624/AD5664

## USING AD5624/AD5664 WITH A GALVANICALLY ISOLATED INTERFACE

In process control applications in industrial environments, it is often necessary to use a galvanically isolated interface to protect and isolate the controlling circuitry from any hazardous common-mode voltages that might occur in the area where the DAC is functioning. Isocouplers provide isolation in excess of 3 kV. The AD5624/AD5664 use a 3-wire serial logic interface, so the ADuM130x 3-channel digital isolator provides the required isolation (see Figure 41). The power supply to the part also needs to be isolated, which is done by using a transformer. On the DAC side of the transformer, a 5 V regulator provides the 5 V supply required for the AD5624/AD5664.

Figure 41. AD5624/AD5664 with a Galvanically Isolated Interface

## POWER SUPPLY BYPASSING AND GROUNDING

When accuracy is important in a circuit, it is helpful to consider carefully the power supply and ground return layout on the board. The printed circuit board containing the AD5624/AD5664 should have separate analog and digital sections, each having its own area of the board. If the AD5624/AD5664 is in a system where other devices require an AGND-to-DGND connection, the connection should be made at one point only. This ground point should be as close as possible to the AD5624/AD5664.

The power supply to the AD5624/AD5664 should be bypassed with 10  $\mu$ F and 0.1  $\mu$ F capacitors. The capacitors should be located as close as possible to the device, with the 0.1  $\mu$ F capacitor ideally right up against the device. The 10  $\mu$ F capacitor is the tantalum bead type. It is important that the 0.1  $\mu$ F capacitor has low effective series resistance (ESR) and effective series inductance (ESI), for example, common ceramic types of capacitors. This 0.1  $\mu$ F capacitor provides a low impedance path to ground for high frequencies caused by transient currents due to internal logic switching.

The power supply line itself should have as large a trace as possible to provide a low impedance path and to reduce glitch effects on the supply line. Clocks and other fast switching digital signals should be shielded from other parts of the board by digital ground. Avoid crossover of digital and analog signals if possible. When traces cross on opposite sides of the board, ensure that they run at right angles to each other to reduce feedthrough effects through the board. The best board layout technique is the microstrip technique where the component side of the board is dedicated to the ground plane only and the signal traces are placed on the solder side. However, this is not always possible with a 2-layer board.
