### **ELECTRICAL CHARACTERISTICS**

**ELECTRICAL CHARACTERISTICS** ( $I_S = 300\mu A \text{ per Amplifier}$ ) The  $\bullet$  denotes the specifications which apply over the specified operating temperature range, otherwise specifications are at  $T_A = 25^{\circ}$ C. For V<sup>+</sup> = 5V, V<sup>-</sup> = -5V:  $R_{SET} = 1M$  to ground,  $A_V = +2$ ,  $R_F = R_G = 11k$ ,  $R_I = 1k$ ; For V<sup>+</sup> = 3V, V<sup>-</sup> = 0V:  $R_{SFT} = 270k$  to V<sup>-</sup>,  $A_V = +2$ ,  $R_F = 9.31k$ ,  $R_G = 9.31k$  to 1.5V,  $R_I = 1k$  to 1.5V unless otherwise specified.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: As long as output current and junction temperature are kept below the absolute maximum ratings, no damage to the part will occur. Depending on the supply voltage, a heat sink may be required.

**Note 3:** The LT6210C/LT6211C is guaranteed functional over the operating temperature range of -40°C to 85°C.

Note 4: The LT6210C/LT6211C is guaranteed to meet specified performance from 0°C to 70°C. The LT6210C/LT6211C is designed, characterized and expected to meet specified performance from -40°C and 85°C but is not tested or QA sampled at these temperatures. The LT6210I/ LT62111 is guaranteed to meet specified performance from –40°C to 85°C.

Note 5: The LT6210 with no metal connected to the V<sup>-</sup> pin has a  $\theta_{JA}$  of 230°C/W, however, thermal resistances vary depending upon the amount of PC board metal attached to Pin 2 of the device. With the LT6210 mounted on a 2500mm<sup>2</sup> 3/32" FR-4 board covered with 2oz copper on both sides and with just 20 mm<sup>2</sup> of copper attached to Pin 2,  $\theta_{JA}$  drops to 160°C/W. Thermal performance can be improved even further by using a 4-layer board or by attaching more metal area to Pin 2.

Thermal resistance of the LT6211 in MSOP-10 is specified for a 2500mm<sup>2</sup> 3/32" FR-4 board covered with 2oz copper on both sides and with 100mm<sup>2</sup> of copper attached to Pin 5. Its performance can also be increased with additional copper much like the LT6210.

To achieve the specified  $\theta_{JA}$  of 43°C/W for the LT6211 DFN-10, the exposed pad must be soldered to the PCB. In this package,  $\theta_{JA}$  will benefit from increased copper area attached to the exposed pad.

 $T_{I}$  is calculated from the ambient temperature  $T_{A}$  and the power dissipation PD according to the following formula:

$$\mathsf{T}_\mathsf{J} = \mathsf{T}_\mathsf{A} + (\mathsf{P}_\mathsf{D} \bullet \Theta_\mathsf{J}_\mathsf{A})$$

The maximum power dissipation can be calculated by:

$$P_{D(MAX)} = (V_{S} \bullet I_{S(MAX)}) + (V_{S}/2)^{2}/R_{LOAD}$$

Note 6: For PSRR and -IPSRR testing, the current into the I<sub>SET</sub> pin is constant, maintaining a consistent LT6210/LT6211 quiescent bias point. A graph of PSRR vs Frequency is included in the Typical Performance Characteristics showing +PSRR and -PSRR with RSFT connecting ISFT to around.

Note 7: While the LT6210 and LT6211 circuitry is capable of significant output current even beyond the levels specified, sustained shortcircuit current exceeding the Absolute Maximum Rating of ±80mA may permanently damage the device.

Note 8: This parameter is guaranteed to meet specified performance through design and characterization. It is not production tested.

Note 9: Differential gain and phase are measured using a Tektronix TSG120YC/NTSC signal generator and a Tektronix 1780R Video Measurement Set. The resolution of this equipment is 0.1% and 0.1°. Five identical amplifier stages were cascaded giving an effective resolution of 0.02% and 0.02°.

Note 10: Input voltage range on ±5V dual supplies is guaranteed by CMRR. On 3V single supply it is guaranteed by design and by correlation to the ±5V input voltage range limits.

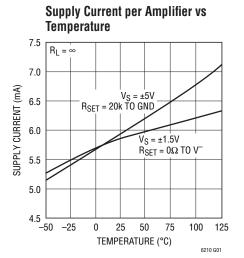

Note 11: This parameter is tested by forcing a 50mV differential voltage between the inverting and noninverting inputs.

## **APPLICATIONS INFORMATION**

### Setting the Quiescent Operating Current (I<sub>SET</sub> Pin)

The quiescent bias point of the LT6210/LT6211 is SET with either an external resistor from the I<sub>SET</sub> pin to a lower potential or by drawing a current out of the ISFT pin. However, the I<sub>SET</sub> pin is not designed to function as a shutdown. The LT6211 uses two entirely independent bias networks, so while each channel can be programmed for a different supply current, neither I<sub>SFT</sub> pin should be left unconnected. A simplified schematic of the internal biasing structure can be seen in Figure 1. Figure 2 illustrates the results of varying R<sub>SET</sub> on 3V and ±5V supplies. Note that shorting the I<sub>SET</sub> pin under 3V operation results in a quiescent bias of approximately 6mA. Attempting to bias the LT6210/LT6211 at a current level higher than 6mA by using a smaller resistor may result in instability and decreased performance. However, internal circuitry clamps the supply current of the part at a safe level of approximately 15mA in case of accidental connection of the I<sub>SFT</sub> pin directly to a negative potential.

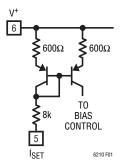

Figure 1. Internal Bias Setting Circuitry

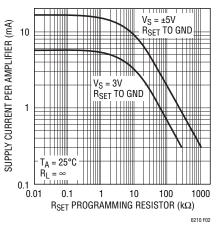

Figure 2. Setting  $R_{SET}$  to Control I<sub>S</sub>

### **Input Considerations**

The inputs of the LT6210/LT6211 are protected by backto-back diodes. If the differential input voltage exceeds 1.4V, the input current should be limited to less than the absolute maximum ratings of  $\pm$ 10mA. In normal operation, the differential voltage between the inputs is small, so the  $\pm$ 1.4V limit is generally not an issue. ESD diodes protect both inputs, so although the part is not guaranteed to function outside the common mode range, input voltages that exceed a diode beyond either supply will also require current limiting to keep the input current below the absolute maximum of  $\pm$ 10mA.

#### Feedback Resistor Selection

The small-signal bandwidth of the LT6210/LT6211 is set by the external feedback resistors and the internal junction capacitances. As a result, the bandwidth is a function of the quiescent supply current, the supply voltage, the value of the feedback resistor, the closed-loop gain and the load resistor. Refer to the Typical AC Performance table for more information.

#### **Layout and Passive Components**

As with all high speed amplifiers, the LT6210/LT6211 require some attention to board layout. Low ESL/ESR bypass capacitors should be placed directly at the positive and negative supply ( $0.1\mu$ F ceramics are recommended). For best transient performance, additional  $4.7\mu$ F tantalums should be added. A ground plane is recommended and trace lengths should be minimized, especially on the inverting input lead.

### **Capacitance on the Inverting Input**

Current feedback amplifiers require resistive feedback from the output to the inverting input for stable operation. Capacitance on the inverting input will cause peaking in the frequency response and overshoot in the transient response. Take care to minimize the stray capacitance at the inverting input to ground and between the output and the inverting input. If significant capacitance is unavoidable in a given application, an inverting gain configuration should be considered. When configured inverting, the amplifier inputs do not slew and the effect of parasitics is greatly reduced.

### **APPLICATIONS INFORMATION**

#### **Capacitive Loads**

The LT6210/LT6211 are stable with any capacitive load. Although peaking and overshoot may result in the AC transient response, the amplifier's compensation decreases bandwidth with increasing output capacitive load to ensure stability. To maintain a response with minimal peaking, the feedback resistor can be increased at the cost of bandwidth as shown in the Typical Performance Characteristics. Alternatively, a small resistor ( $5\Omega$  to  $35\Omega$ ) can be put in series with the output to isolate the capacitive load from the amplifier output. This has the advantage that the amplifier bandwidth is only reduced when the capacitive load is present. The disadvantage of this technique is that the gain is a function of the load resistance.

#### **Power Supplies**

The LT6210/LT6211 will operate on single supplies from 3V to 12V and on split supplies from  $\pm 1.5$ V to  $\pm 6$ V. If split supplies of unequal absolute value are used, input offset voltage and inverting input current will shift from the values specified in the Electrical Characteristics table. Input offset voltage will shift 2mV and inverting input current will shift 0.5µA for each volt of supply mismatch.

#### Slew Rate

Unlike a traditional voltage feedback op amp, the slew rate of a current feedback amplifier is not independent of the amplifier gain configuration. In a current feedback amplifier, both the input stage and the output stage have slew rate limitations. In the inverting mode, and for gains of 2 or more in the noninverting mode, the signal amplitude between the input pins is small and the overall slew rate is that of the output stage. For gains less than 2 in the noninverting mode, the overall slew rate is limited by the input stage. The input slew rate of the LT6210/LT6211 on  $\pm$ 5V supplies with an R<sub>SFT</sub> resistor of 20k (I<sub>S</sub> = 6mA) is approximately 600V/µs and is set by internal currents and capacitances. The output slew rate is additionally constrained by the value of the feedback resistor and internal capacitance. At a gain of 2 with  $887\Omega$  feedback and gain resistors, ±5V supplies and the same biasing as above, the output slew rate is typically 700V/µs. Larger feedback resistors, lower supply voltages and lower supply current levels will all reduce slew rate. Input slew rates significantly exceeding the output slew capability can actually decrease slew performance in a positive gain configuration; the cleanest transient response will be obtained from input signals with slew rates slower than 1000V/µs.

### **Output Swing and Drive**

The output stage of the LT6210/LT6211 consists of a pair of class-AB biased common emitters that enable the output to swing rail-to-rail. Since the amplifiers can potentially deliver output currents well beyond the specified minimum short-circuit current, care should be taken not to short the output of the device indefinitely. Attention must be paid to keep the junction temperature of the IC below the absolute maximum rating of 150°C if the output is used to drive low impedance loads. See Note 5 for details. Additionally, the output of the amplifier has reverse-biased ESD diodes connected to each supply. If the output is forced beyond either supply, large currents will flow through these diodes. If the current is limited to 80mA or less, no damage to the part will occur.

### TYPICAL APPLICATIONS

### **3V Cable Driver with Active Termination**

Driving back-terminated cables on single supplies usually results in very limited signal amplitude at the receiving end of the cable. However, positive feedback can be used to reduce the size of the series back termination resistor, thereby decreasing the attenuation between the series and shunt termination resistors while still maintaining controlled output impedance from the line-driving amplifier. Figure 3 shows the LT6210 using this "active termination" scheme on a single 3V supply. The amplifier is AC-coupled and in an inverting gain configuration to maximize the input

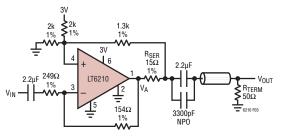

Figure 3. 3V Cable Driver with Active Termination

signal range. The gain from V<sub>IN</sub> to the receiving end of the cable, V<sub>OUT</sub>, is set to -1. The effective impedance looking into the amplifier circuit from the cable is  $50\Omega$  throughout the usable bandwidth.

The response of the cable driver with a 1MHz sinusoid is shown in Figure 4. The circuit is capable of transmitting a  $1.5V_{P-P}$  undistorted sinusoid to the  $50\Omega$  termination resistor and has a full signal  $1V_{P-P}$  bandwidth of 50MHz. Small signal –3dB bandwidth extends from 1kHz to 56MHz with the selected coupling capacitors.

### TYPICAL APPLICATION

#### Line Driver with Power Saving Mode

In applications where low distortion or high slew rate are desirable but not necessary at all times, it may be possible to decrease the LT6210 or LT6211's quiescent current when the higher power performance is not required. Figure 5 illustrates a method of setting guiescent current with a FET switch. In the 5V dual supply case pictured, shorting the ISFT pin through an effective 20k to ground sets the supply current to 6mA, while the 240k resistor at the ISFT pin with the FET turned off sets the supply current to approximately 1mA. The feedback resistor of 4.02k is selected to minimize peaking in low power mode. The bandwidth

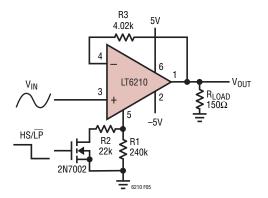

Figure 5. Line Driver with Low Power Mode

of the LT6210 in this circuit increases from about 40MHz in low power mode to over 200MHz in full speed mode. as illustrated in Figure 6. Other AC specs also improve significantly at the higher current setting. The following table shows harmonic distortion at 1MHz with a 2VP-P sinusoid at the two selected current levels.
