Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: T_J is calculated from the ambient temperature T_A and power dissipation P_D as follows:

$$T_J = T_A + (P_D \cdot 110^\circ\text{C/W})$$

Note 3: The LTC3878 is tested in a feedback loop that adjusts V_{FB} to achieve a specified error amplifier output voltage (I_{TH}).

Note 4: The LTC3878E is guaranteed to meet specifications from 0°C to 85°C . Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3878I is guaranteed to meet specifications over the full -40°C to 85°C operating temperature range.

Note 5: Rise and fall time are measured using 10% and 90% levels. Delay times are measured using 50% levels.

PIN FUNCTIONS

RUN/SS (Pin 1): Run Control and Soft-Start Input. A capacitor to ground on this pin sets the ramp time to full output current (approximately $3s/\mu F$) when RUN/SS is open. The switching outputs are disabled when below 1.5V. The device is in micropower shutdown when under 0.7V. If left open, there is an internal 1.2 μA pull-up current on RUN/SS. INTV_{CC} is enabled when RUN/SS exceeds 0.7V.

PGOOD (Pin 2): Power Good Output. This open-drain logic output is pulled to ground when the output voltage is outside of a $\pm 7.5\%$ window around the regulation point.

V_{RNG} (Pin 3): V_{DS} Sense Voltage Range Input. The maximum allowed bottom MOSFET V_{DS} sense voltage between SW and PGND is equal to $(0.133)V_{RNG}$. The voltage applied to V_{RNG} can be any value between 0.2V and 2V. If V_{RNG} is tied to SGND, the device operates with a maximum valley current sense threshold of 93mV typical. If V_{RNG} is tied to INTV_{CC}, the device operates with a maximum valley current sense threshold of 186mV typical.

FCB (Pin 4): Forced Continuous Input. Connect this pin to INTV_{CC} to enable discontinuous mode for light load operation. Connect this pin to SGND to force continuous mode operation in all conditions.

I_{TH} (Pin 5): Current Control Threshold and Error Amplifier Compensation Point. The current comparator threshold increases with this control voltage. The voltage ranges from 0V to 2.4V, with 0.8V corresponding to zero sense voltage (zero current).

SGND (Pin 6): Signal Ground. All small-signal components should be connected to SGND. Connect SGND to PGND using a single PCB trace.

I_{ON} (Pin 7): On-Time Current Input. Tie a resistor from V_{IN} to this pin to set the one-shot timer current and thus the switching frequency.

V_{FB} (Pin 8): Error Amplifier Feedback Input. This pin connects the error amplifier to an external resistive divider from V_{OUT}.

NC (Pin 9): For factory use only. Can be connected to any voltage equal to or less than INTV_{CC}.

V_{IN} (Pin 10): Main Input Supply. The supply voltage can range from 4V to 38V. For increased noise immunity decouple this pin to PGND with an RC filter.

INTV_{CC} (Pin 11): Internal 5.3V Regulator Output. The driver and control circuits are powered from this voltage. Decouple this pin to PGND with a minimum of 1 μF , 10V X5R or X7R ceramic capacitor.

BG (Pin 12): Bottom Gate Drive. This pin drives the gate of the bottom N-Channel power MOSFET between PGND and INTV_{CC}.

PGND (Pin 13): Power Ground. Connect this pin as close as practical to the source of the bottom N-channel power MOSFET, the (–) terminal of C_{INTVCC} and the (–) terminal of C_{VIN}.

SW (Pin 14): Switch Node. The (–) terminal of the bootstrap capacitor, C_B, connects to this node. This pin swings from a diode voltage below ground up to V_{IN}.

TG (Pin 15): Top Gate Drive. This pin drives the gate of the top N-channel power MOSFET between SW and BOOST.

BOOST (Pin 16): Boosted Floating Driver Supply. The (+) terminal of the bootstrap capacitor, C_B, connects to this node. This node swings from $(INTV_{CC} - V_{SCHOTTKY})$ to $V_{IN} + (INTV_{CC} - V_{SCHOTTKY})$.

FUNCTIONAL DIAGRAM

OPERATION

LTC1778 Compatibility

The LTC3878 is compatible with the LTC1778 in applications which do not use the EXT V_{CC} function. The LTC3878 offers improved gate drive and reduced dead time, which allows higher efficiency than the LTC1778. On the LTC1778 Pin 9 is EXT V_{CC} , but on the LTC3878 it is a no connect. The other notable difference is that the shutdown latch-off timer is removed. The LTC3878 should be a drop in, pin-for-pin replacement in most applications that do not use EXT V_{CC} . The LTC3878 should be tested and verified in each application without assuming compatibility. Contact a Linear applications expert to answer any questions regarding LTC3878/LTC1778 compatibility.

Main Control Loop

The LTC3878 is a valley current mode controller IC for use in DC/DC step-down converters. In normal continuous operation, the top MOSFET is turned on for a fixed interval determined by a one-shot timer, OST. When the top MOSFET is turned off, the bottom MOSFET is turned on until the current comparator, I $_{CMP}$, trips, restarting the one-shot timer and initiating the next cycle. Inductor valley current is measured by sensing the voltage between the PGND and SW pins using the bottom MOSFET on-resistance. The voltage on the I $_{TH}$ pin sets the comparator threshold corresponding to inductor valley current. The error amplifier EA adjusts this voltage by comparing the feedback signal V_{FB} from the output voltage to the feedback reference voltage V_{FBREF} . Increasing the load current causes a drop in the feedback voltage relative to the reference. The EA senses the feedback voltage drop and adjusts the I $_{TH}$ voltage higher until the average inductor current matches the load current.

With DC current loads less than 1/2 of the peak-to-peak ripple the inductor current can drop to zero or become negative. In discontinuous operation, negative inductor

current is detected and prevented by the current reversal comparator I $_{REV}$, which shuts off MB. Both switches remain off with the output capacitor supplying the load current until the EA moves the I $_{TH}$ voltage above the zero current level (0.8V) to initiate another switching cycle. When the FCB (forced continuous bar) pin is below the internal FCB threshold reference, V_{FCB} , the regulator is forced to operate in continuous mode by disabling reversal comparator, I $_{REV}$, thereby allowing the inductor current to become negative.

The continuous mode operating frequency can be determined by dividing the calculated duty cycle, V_{OUT}/V_{IN} , by the fixed on-time. The OST generates an on-time proportional to the ideal duty cycle, thus holding the frequency approximately constant with changes in V_{IN} . The nominal frequency can be adjusted with an external resistor, R $_{ON}$.

Foldback current limiting is provided to protect against low impedance shorts. If the controller is in current limit and V_{OUT} drops to less 50% of regulation, the current limit set-point “folds back” to progressively lower values. To recover from foldback current limit, the excessive load or low impedance short needs to be removed.

Pulling the RUN/SS pin low forces the controller into its shutdown state, turning off both MT and MB. Releasing the pin allows an internal 1.2 μ A current source to charge up an external soft-start capacitor, C $_{SS}$. When the RUN/SS pin is less than 0.7V, the device is in the low power shutdown condition with a nominal bias current of 18 μ A. When RUN/SS is greater than 0.7V and less than 1.5V, INT V_{CC} and all internal circuitry are enabled while MT and MB are forced off. Current-limited soft-start begins when RUN/SS exceeds 1.5V. Normal operation at full current limit is achieved at approximately 3V on RUN/SS. Foldback current limit is defeated during soft-start.

APPLICATIONS INFORMATION

The basic LTC3878 application circuit is shown on the first page of this data sheet. External component selection is largely determined by maximum load current and begins with the selection of sense resistance and power MOSFET switches. The LTC3878 uses the on-resistance of the synchronous power MOSFET to determine the inductor current. The desired ripple current and operating frequency largely determines the inductor value. Finally, C_{IN} is selected for its ability to handle the large RMS current into the converter, and C_{OUT} is chosen with low enough ESR to meet output voltage ripple and transient specifications.

Maximum V_{DS} Sense Voltage and V_{RNG} Pin

Inductor current is measured by sensing the bottom MOSFET V_{DS} voltage that appears between the PGND and SW pins. The maximum allowed V_{DS} sense voltage is set by the voltage applied to the V_{RNG} pin and is approximately equal to $(0.133)V_{RNG}$. The current mode control loop does not allow the inductor current valleys to exceed $(0.133)V_{RNG}$. In practice, one should allow margin, to account for variations in the LTC3878 and external component values. A good guide for setting V_{RNG} is:

$$V_{RNG} = 7.5 \cdot (\text{Maximum } V_{DS} \text{ Sense Voltage})$$

An external resistive divider from $INTV_{CC}$ can be used to set the voltage on the V_{RNG} pin between 0.2V and 2V, resulting in peak sense voltages between 26.6mV and 266mV. The wide peak voltage sense range allows for a variety of applications and MOSFET choices. The V_{RNG} pin can also be tied to either SGND or $INTV_{CC}$ to force internal defaults. When V_{RNG} is tied to SGND, the device operates at a valley current sense threshold of 93mV typical. If V_{RNG} is tied to $INTV_{CC}$, the device operates at a valley current sense threshold of 186mV typical.

Power MOSFET Selection

The LTC3878 requires two external N-channel power MOSFETs, one for the top (main) switch and one for the bottom (synchronous) switch. Important parameters for the power MOSFETs are the breakdown voltage $V_{BR(DSS)}$, threshold voltage $V_{GS(TH)}$, on-resistance $R_{DS(ON)}$, reverse transfer capacitance C_{RSS} and maximum current $I_{DS(MAX)}$.

The gate drive voltages are set by the 5.3V $INTV_{CC}$ supply. Consequently, logic-level threshold MOSFETs must be used in LTC3878 applications. If the input voltage is expected to drop below 5V, then sub-logic level threshold MOSFETs should be considered.

Using the bottom MOSFET as the current sense element requires particular attention be paid to its on-resistance. MOSFET on-resistance is typically specified with a maximum value $R_{DS(ON)(MAX)}$ at 25°C. In this case additional margin is required to accommodate the rise in MOSFET on-resistance with temperature.

$$R_{DS(ON)(MAX)} = \frac{\text{Max } V_{DS} \text{ Sense Voltage}}{I_{OUT} \cdot \rho_T}$$

The ρ_T term is a normalization factor (unity at 25°C) accounting for the significant variation in on-resistance with temperature, typically about 0.4%/°C, as shown in Figure 1. For a maximum junction temperature of 100°C using a value of $\rho_T = 1.3$ is reasonable.

The power dissipated by the top and bottom MOSFETs depends upon their respective duty cycles and the load current. When the LTC3878 is operating in continuous mode, the duty cycles for the MOSFETs are:

$$D_{TOP} = \frac{V_{OUT}}{V_{IN}}$$

$$D_{BOT} = \frac{V_{IN} - V_{OUT}}{V_{IN}}$$

Figure 1. $R_{DS(ON)}$ vs Temperature

APPLICATIONS INFORMATION

The resulting power dissipation in the MOSFETs at maximum output current are:

$$P_{TOP} = D_{TOP} \cdot I_{OUT(MAX)}^2 \cdot P_{\tau(TOP)} \cdot R_{DS(ON)(MAX)} + V_{IN}^2 \left(\frac{I_{OUT(MAX)}}{2} \right) (C_{MILLER}) \left[\frac{DR_{TGHIGH}}{V_{INTVCC} - V_{MILLER}} + \frac{DR_{TGLow}}{V_{MILLER}} \right] f_{OSC}$$

$$P_{BOT} = D_{BOT} \cdot I_{OUT(MAX)}^2 \cdot P_{\tau(BOT)} \cdot R_{DS(ON)(MAX)}$$

DR_{TGHIGH} is pull-up driver resistance and DR_{TGLow} is the TG driver pull-down resistance. V_{MILLER} is the Miller effect V_{GS} voltage and is taken graphically from the power MOSFET data sheet.

MOSFET input capacitance is a combination of several components but can be taken from the typical “gate charge” curve included on the most data sheets (Figure 2). The curve is generated by forcing a constant input current into the gate of a common source, current source, loaded stage and then plotting the gate versus time. The initial slope is the effect of the gate-to-source and gate-to-drain capacitance. The flat portion of the curve is the result of the Miller multiplication effect of the drain-to-gate capacitance as the drain drops the voltage across the current source load. The upper sloping line is due to the drain-to-gate accumulation capacitance and the gate-to-source capacitance. The Miller charge (the increase in coulombs on the horizontal axis from a to b while the curve is flat) is specified from a given V_{DS} drain voltage, but can be adjusted for different V_{DS} voltages by multiplying by the ratio of the application V_{DS} to the curve specified V_{DS} values. A way to estimate the C_{MILLER} term is to take the change in gate charge from points a and b or the parameter Q_{GD} on a manufacturers data sheet and divide by the specified V_{DS} test voltage, $V_{DS(TEST)}$.

$$C_{MILLER} = \frac{Q_{GD}}{V_{DS(TEST)}}$$

C_{MILLER} is the most important selection criteria for determining the transition loss term in the top MOSFET but is not directly specified on MOSFET data sheets.

Figure 2. Gate Charge Characteristic

Both MOSFETs have I^2R power loss, and the top MOSFET includes an additional term for transition loss, which are highest at high input voltages. For $V_{IN} < 20V$, the high current efficiency generally improves with larger MOSFETs, while for $V_{IN} > 20V$, the transition losses rapidly increase to the point that the use of a higher $R_{DS(ON)}$ device with lower C_{MILLER} actually provides higher efficiency. The synchronous MOSFET losses are greatest at high input voltage when the top switch duty factor is low or during a short-circuit when the synchronous switch is on close to 100% of the period.

Operating Frequency

The choice of operating frequency is a tradeoff between efficiency and component size. Lowering the operating frequency improves efficiency by reducing MOSFET switching losses but requires larger inductance and/or capacitance to maintain low output ripple voltage. Conversely, raising the operating frequency degrades efficiency but reduces component size.

The operating frequency of LTC3878 applications is determined implicitly by the one-shot timer that controls the on-time, t_{ON} , of the top MOSFET switch. The on-time is set by the current into the I_{ON} pin according to:

$$t_{ON} = \frac{0.7V}{I_{ON}} (10pF)$$

Tying a resistor R_{ON} from V_{IN} to the I_{ON} pin yields an on-time inversely proportional to V_{IN} . For a step-down converter, this results in pseudo fixed frequency operation as the input supply varies.

$$f_{OP} = \frac{V_{OUT}}{0.7V \cdot R_{ON} (10pF)} [Hz]$$

APPLICATIONS INFORMATION

Figure 3 shows how R_{ON} relates to switching frequency for several common output voltages.

When designing for pseudo fixed frequency, there is systematic error because the I_{ON} pin voltage is approximately 0.7V, not zero. This causes the I_{ON} current to be inversely proportional to $(V_{IN} - 0.7V)$ and not V_{IN} . The I_{ON} current error increases as V_{IN} decreases. To correct this error, an additional resistor R_{ON2} can be connected from the I_{ON} pin to the 5.3V $INTV_{CC}$ supply.

$$R_{ON2} = \frac{5.3V - 0.7V}{0.7V} R_{ON}$$

Figure 3. Switching Frequency vs R_{ON}

Minimum Off-Time and Dropout Operation

The minimum off-time, $t_{OFF(MIN)}$, is the shortest time required for the LTC3878 to turn on the bottom MOSFET, trip the current comparator and then turn off the bottom MOSFET. This time is typically about 220ns. The minimum off-time limit imposes a maximum duty cycle of $t_{ON} / (t_{ON} + t_{OFF(MIN)})$. If the maximum duty cycle is reached, due to a drooping input voltage for example, then the output will drop out of regulation. The minimum input voltage to avoid dropout is:

$$V_{IN(MIN)} = V_{OUT} \frac{t_{ON} + t_{OFF(MIN)}}{t_{ON}}$$

A plot of maximum duty cycle vs. frequency is shown in Figure 4.

Figure 4. Maximum Switching Frequency vs Duty Cycle

Likewise, the maximum frequency of operation is determined by the fixed on-time, t_{ON} , and the minimum off-time, $t_{OFF(MIN)}$. The fixed on-time is determined by dividing the duty factor by the nominal frequency of operation:

$$f_{MAX} = \frac{1}{\frac{V_{OUT}}{V_{IN} \cdot f_{OP}} + t_{OFF(MIN)}} \text{ [Hz]}$$

The LTC3878 is a PFM (pulse frequency mode) regulator where pulse density is modulated, not pulse width. Consequently, frequency increases with a load step and decreases with a load release. The steady-state operating frequency, f_{OP} , should be set sufficiently below f_{MAX} to allow for device tolerances and transient response.

Inductor Value Calculation

Given the desired input and output voltages, the inductor value and operation frequency determine the ripple current:

$$\Delta I_L = \left(\frac{V_{OUT}}{f_{OP} \cdot L} \right) \left(1 - \frac{V_{OUT}}{V_{IN}} \right)$$

Lower ripple current reduces core losses in the inductor, ESR losses in the output capacitors and output voltage ripple. Highest efficiency operation is obtained at low frequency with small ripple current. However, achieving this requires a large inductor. There is a trade-off between component size, efficiency and operating frequency.

APPLICATIONS INFORMATION

A reasonable starting point is to choose a ripple current that is about 40% of $I_{OUT(MAX)}$. The largest ripple current occurs at the highest V_{IN} . To guarantee that ripple current does not exceed a specified maximum, the inductance should be chosen according to:

$$L = \left(\frac{V_{OUT}}{f_{OP} \cdot \Delta I_{L(MAX)}} \right) \left(1 - \frac{V_{OUT}}{V_{IN(MAX)}} \right)$$

Once the value for L is known, the type of inductor must be selected. High efficiency converters generally cannot tolerate the core loss of low cost powdered iron cores, forcing the use of more expensive ferrite materials such as molypermalloy or Kool Mμ cores. A variety of inductors designed for high current, low voltage applications are available from manufacturers such as Sumida, Panasonic, Coiltronics, Coilcraft, Toko, Vishay, Pulse and Würth.

Inductor Core Selection

Once the inductance value is determined, the type of inductor must be selected. Core loss is independent of core size for a fixed inductor value, but it is very dependent on inductance selected. As inductance increases, core losses go down. Unfortunately, increased inductance requires more turns of wire and therefore copper losses will increase.

Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can concentrate on copper loss and preventing saturation. Ferrite core material saturates “hard,” which means that inductance collapses abruptly when the peak design current is exceeded. This results in an abrupt increase in inductor ripple current and consequent output voltage ripple. Do not allow the core to saturate!

C_{IN} and C_{OUT} Selection

The input capacitance C_{IN} is required to filter the square wave current at the drain of the top MOSFET. Use a low ESR capacitor sized to handle the maximum RMS current.

$$I_{RMS} \cong I_{OUT(MAX)} \cdot \frac{V_{OUT}}{V_{IN}} \cdot \sqrt{\frac{V_{IN}}{V_{OUT}}} - 1$$

This formula has a maximum at $V_{IN} = 2V_{OUT}$, where $I_{RMS} = I_{OUT(MAX)}/2$. This simple worst-case condition is commonly used for design because even significant deviations do not offer much relief. Note that ripple current ratings from capacitor manufacturers are often based on only 2000 hours of life, which makes it advisable to de-rate the capacitor.

The selection of C_{OUT} is primarily determined by the ESR required to minimize voltage ripple and load step transients. The ΔV_{OUT} is approximately bounded by:

$$\Delta V_{OUT} \leq \Delta I_L \left(ESR + \frac{1}{8 \cdot f_{OP} \cdot C_{OUT}} \right)$$

Since ΔI_L increases with input voltage, the output ripple is highest at maximum input voltage. Typically, once the ESR requirement is satisfied, the capacitance is adequate for filtering and has the necessary RMS current rating.

Multiple capacitors placed in parallel may be needed to meet the ESR and RMS current handling requirements. Dry tantalum, specialty polymer, aluminum electrolytic and ceramic capacitors are all available in surface mount packages. Specialty polymer capacitors offer very low ESR but have lower specific capacitance than other types. Tantalum capacitors have the highest specific capacitance but it is important to only use types that have been surge tested for use in switching power supplies. Aluminum electrolytic capacitors have significantly higher ESR, but can be used in cost-sensitive applications providing that consideration is given to ripple current ratings and long-term reliability. Ceramic capacitors have excellent low ESR characteristics but can have a high voltage co-efficient and audible piezoelectric effects. The high Q of ceramic capacitors with trace inductance can also lead to significant ringing. When used as input capacitors, care must be taken to ensure that ringing from inrush currents and switching does not pose an overvoltage hazard to the power switches and controller. To dampen input voltage transients, add a small 5μF to 40μF aluminum electrolytic capacitor with an ESR in the range of 0.5Ω to 2Ω. High performance through-hole capacitors may also be used, but an additional ceramic capacitor in parallel is recommended to reduce the effect of lead inductance.

APPLICATIONS INFORMATION

Top MOSFET Driver Supply (C_B , D_B)

An external bootstrap capacitor, C_B , connected to the BOOST pin supplies the gate drive voltage for the topside MOSFET. This capacitor is charged through diode D_B from $INTV_{CC}$ when the switch node is low. When the top MOSFET turns on, the switch node rises to V_{IN} and the BOOST pin rises to approximately $V_{IN} + INTV_{CC}$. The boost capacitor needs to store approximately 100 times the gate charge required by the top MOSFET. In most applications 0.1 μ F to 0.47 μ F, X5R or X7R dielectric capacitor is adequate.

It is recommended that the BOOST capacitor be no larger than 10% of the $INTV_{CC}$ capacitor C_{VCC} , to ensure that the C_{VCC} can supply the upper MOSFET gate charge and BOOST capacitor under all operating conditions. Variable frequency in response to load steps offers superior transient performance but requires higher instantaneous gate drive. Gate charge demands are greatest in high frequency low duty factor applications under high di/dt load steps and at start-up.

Setting Output Voltage

The LTC3878 output voltage is set by an external feedback resistive divider carefully placed across the output, as shown in Figure 5. The regulated output voltage is determined by:

$$V_{OUT} = 0.8V \left(1 + \frac{R_B}{R_A} \right)$$

To improve the transient response, a feed-forward capacitor, C_{FF} , may be used. Great care should be taken to route the V_{FB} line away from noise sources, such as the inductor or the SW line.

Figure 5. Setting Output Voltage

Discontinuous Mode Operation and FCB Pin

The FCB (forced continuous bar) pin determines whether the LTC3878 operates in forced continuous mode or allows discontinuous conduction mode. Tying this pin above 0.8V enables discontinuous operation, where the bottom MOSFET turns off when the inductor current reverses polarity. The load current at which current reverses and discontinuous operation begins depends on the amplitude of the inductor ripple current and will vary with changes in V_{IN} . In steady-state operation, discontinuous conduction mode occurs for DC load currents less than 1/2 the peak-to-peak ripple current. Tying the FCB pin below the 0.8V threshold forces continuous switching, where inductor current is allowed to reverse at light loads and maintain synchronous switching.

In addition to providing a logic input to force continuous operation, the FCB pin provides a means to maintain a fly back winding output when the primary is operating in discontinuous mode. The secondary output V_{OUT2} is normally set as shown in Figure 6 by the turns ratio N of the transformer. However, if the controller goes into discontinuous mode and halts switching due to a light primary load current, then V_{OUT2} will droop. An external resistor divider from V_{OUT2} to the FCB pin sets a minimum voltage $V_{OUT2(MIN)}$ below which continuous operation is forced until V_{OUT2} has risen above its minimum.

$$V_{OUT2(MIN)} = 0.8V \left(1 + \frac{R_4}{R_3} \right)$$

Figure 6. Secondary Output Loop

APPLICATIONS INFORMATION

Fault Conditions: Current Limit and Foldback

The maximum inductor current is inherently limited in a current mode controller by the maximum sense voltage. In the LTC3878, the maximum sense voltage is controlled by the voltage on the V_{RNG} pin. With valley current mode control, the maximum sense voltage and the sense resistance determine the maximum allowed inductor valley current. The corresponding output current limit is:

$$I_{\text{LIMIT}} = \frac{V_{\text{SNS(MAX)}}}{R_{\text{DS(ON)}} \cdot \rho_T} + \frac{1}{2} \cdot \Delta I_L$$

The current limit value should be checked to ensure that $I_{\text{LIMIT(MIN)}} > I_{\text{OUT(MAX)}}$. The current limit value should be greater than the inductor current required to produce maximum output power at the worst-case efficiency. Worst-case efficiency typically occurs at the highest V_{IN} and highest ambient temperature. It is important to check for consistency between the assumed MOSFET junction temperatures and the resulting value of I_{LIMIT} which heats the MOSFET switches.

Caution should be used when setting the current limit based on the $R_{\text{DS(ON)}}$ of the MOSFETs. The maximum current limit is determined by the minimum MOSFET on-resistance. Data sheets typically specify nominal and maximum values for $R_{\text{DS(ON)}}$ but not a minimum. A reasonable assumption is that the minimum $R_{\text{DS(ON)}}$ lies the same amount below the typical value as the maximum lies above it. Consult the MOSFET manufacturer for further guidelines.

To further limit current in the event of a short circuit to ground, the LTC3878 includes foldback current limiting. If the output falls by more than 50%, then the maximum sense voltage is progressively lowered to about one-sixth of its full value.

INTV_{CC} Regulator

An internal P-channel low dropout regulator produces the 5.3V supply that powers the drivers and internal circuitry within the LTC3878. The INTV_{CC} pin can supply up to 50mA RMS and must be bypassed to ground with a minimum of 1μF low ESR tantalum or ceramic capacitor (10V, X5R or X7R). Output capacitance greater than 10μF is discouraged. Good bypassing is necessary to supply the high transient currents required by the MOSFET gate drivers.

Applications using large MOSFETs with a high input voltage and high frequency of operation may cause the LTC3878 to exceed its maximum junction temperature rating or RMS current rating. In continuous mode operation, this current is $I_{\text{GATECHG}} = f_{\text{OP}}(Q_{\text{g(TOP)}} + Q_{\text{g(BOT)}})$. The junction temperature can be estimated from the equations given in Note 2 of the Electrical Characteristics. For example, with a 30V input supply, the LTC3878 is limited to less than 16.5mA:

$$T_J = 70^\circ\text{C} + (16.5\text{mA})(30)(110^\circ\text{C/W}) = 125^\circ\text{C}$$

Using the INTV_{CC} regulator to supply external loads greater than 5mA is discouraged. INTV_{CC} is designed to supply the LTC3878 with minimal external loading. When using the regulator to supply larger external loads, carefully consider all operating load conditions. During load steps and soft-start, transient current requirements significantly exceed the RMS values. Additional loading on INTV_{CC} takes away from the drive available to source gate charge during high frequency transient load steps.

Soft-Start with the RUN/SS Pin

The RUN/SS pin both enables the LTC3878 and provides a means of programmable current limited soft-start. Pulling the RUN/SS pin below 0.7V puts the LTC3878 into a low quiescent current shutdown ($I_Q < 15\mu\text{A}$). Releasing the pin allows an internal 1.2μA current source to charge up the external timing capacitor C_{SS} . If RUN/SS has been pulled all the way to ground, there is a delay before starting. This delay is created by charging C_{SS} from ground to 1.5V through a 1.2μA current source.

$$t_{\text{DELAY}} = \frac{1.5\text{V}}{1.2\mu\text{A}} \cdot C_{\text{SS}} = (1.3\text{s}/\mu\text{F})C_{\text{SS}}$$

When the voltage on RUN/SS reaches 1.5V, the LTC3878 begins to switch. I_{TH} is clamped to be no greater than RUN/SS – 0.6V, and the device begins switching when I_{TH} exceeds 0.9V. As the RUN/SS voltage rises to 3V, the clamp on I_{TH} increases until it reaches the full-scale 2.4V limit after an additional delay of 1.3s/μF. During this time, the soft-start current limit is set to:

$$I_{\text{LIMIT(SS)}} = I_{\text{LIMIT}} \cdot \frac{(\text{RUN/SS} - 0.6\text{V}) - 0.8\text{V}}{2.4\text{V} - 0.8\text{V}}$$

APPLICATIONS INFORMATION

Regulator output current is negative when I_{TH} is between 0V and 0.8V and positive when I_{TH} is between 0.8V and the maximum full-scale set-point of 2.4V. In normal operating conditions the RUN/SS pin will continue to charge positive until the voltage is equal to $INTV_{CC}$.

INTV_{CC} Undervoltage Lockout

Whenever $INTV_{CC}$ drops below approximately 3.4V, the device enters undervoltage lockout (UVLO). In a UVLO condition, the switching outputs TG and BG are disabled. At the same time, the RUN/SS pin is pulled down from $INTV_{CC}$ to 0.8V with a 3 μ A current source. When the $INTV_{CC}$ UVLO condition is removed, RUN/SS ramps from 0.8V and begins a normal current limited soft-start. This feature is important when regulator start-up is not initiated by applying a logic drive to RUN/SS. Soft-start from $INTV_{CC}$ UVLO release greatly reduces the possibility for start-up oscillations caused by the regulator starting up at $INTV_{CC(UVLOR)}$ and then shutting down at $INTV_{CC(UVLO)}$ due to inrush current.

Efficiency Considerations

The percent efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Although all dissipative elements in the circuit produce losses, four main sources account for most of the losses in LTC3878 circuits.

1. DC I^2R losses. These arise from the resistances of the MOSFETs, inductor and PC board traces and cause the efficiency to drop at high output currents. In continuous mode the average output current flows through the inductor L, but is chopped between the top and bottom MOSFETs. If the two MOSFETs have approximately the same $R_{DS(ON)}$, then the resistance of one MOSFET can simply be summed with the resistances of L and the board traces to obtain the DC I^2R loss. For example, if $R_{DS(ON)} = 0.01\Omega$ and $R_L = 0.005\Omega$, the loss will range from 15mW to 1.5W as the output current varies from 1A to 10A.

2. Transition loss. This loss arises from the brief amount of time the top MOSFET spends in the saturated region during switch node transitions. It depends upon the

input voltage, load current, driver strength and MOSFET capacitance, among other factors. The loss is significant at input voltages above 20V.

3. $INTV_{CC}$ current. This is the sum of the MOSFET driver and control currents.

4. C_{IN} loss. The input capacitor has the difficult job of filtering the large RMS input current to the regulator. It must have a very low ESR to minimize the AC I^2R loss and sufficient capacitance to prevent the RMS current from causing additional upstream losses in fuses or batteries.

Other losses, which include the C_{OUT} ESR loss, bottom MOSFET reverse recovery loss and inductor core loss generally account for less than 2% additional loss.

When making adjustments to improve efficiency, the input current is the best indicator of changes in efficiency. If you make a change and the input current decreases, then the efficiency has increased. If there is no change in input current there is no change in efficiency.

Checking Transient Response

The regulator loop response can be checked by looking at the load transient response. Switching regulators take several cycles to respond to a step in load current. When a load step occurs, V_{OUT} immediately shifts by an amount equal to ΔI_{LOAD} (ESR), where ESR is the effective series resistance of C_{OUT} . ΔI_{LOAD} also begins to charge or discharge C_{OUT} , generating a feedback error signal used by the regulator to return V_{OUT} to its steady-state value. During this recovery time, V_{OUT} can be monitored for overshoot or ringing that would indicate a stability problem. The I_{TH} pin external components shown in the Design Example will provide adequate compensation for most applications.

A rough compensation check can be made by calculating the gain crossover frequency, f_{GCO} . $g_{m(EA)}$ is the error amplifier transconductance, R_C is the compensation resistor and feedback divider attenuation is assumed to be $0.8V/V_{OUT}$. This equation assumes that no feed-forward compensation is used on feedback and that C_{OUT} sets the dominant output pole.

$$f_{GCO} = g_{m(EA)} \cdot R_C \cdot \frac{I_{LIMIT}}{1.6} \cdot \frac{1}{2 \cdot \pi \cdot C_{OUT}} \cdot \frac{0.8}{V_{OUT}}$$

APPLICATIONS INFORMATION

As a rule of thumb the gain crossover frequency should be less than 20% of the switching frequency. For a detailed explanation of switching control loop theory see Application Note 76.

High Switching Frequency Operation

Special care should be taken when operating at switching frequencies greater than 800kHz. At high switching frequencies there may be an increased sensitivity to PCB noise which may result in off-time variation greater than normal. This off-time instability can be prevented in several ways. First, carefully follow the recommended layout techniques. Second, use 2 μ F or more of X5R or X7R ceramic input capacitance per Amps of load current. Third, if necessary, increase the bottom MOSFET ripple voltage to 30mV_{P-P} or greater. This ripple voltage is equal to $R_{DS(ON)}$ typical at 25°C • I_{P-P} .

Design Example

Figure 7 is a power supply design example with the following specifications: V_{IN} = 4.5V to 28V (12V nominal), V_{OUT} = 1.2V \pm 5%, $I_{OUT(MAX)}$ = 15A and f = 400kHz. Start by calculating the timing resistor, R_{ON} :

$$R_{ON} = \frac{1.2V}{0.7V \cdot 400kHz \cdot 10pF} = 429k$$

Select the nearest standard resistor value of 432k for a nominal operating frequency of 396kHz. Set the inductor value to give 35% ripple current at maximum V_{IN} using the adjusted operating frequency:

$$L = \frac{1.2V}{396kHz \cdot 0.35 \cdot 15A} \left(1 - \frac{1.2}{28} \right) = 0.55\mu H$$

Select 0.56 μ H which is the nearest value.

The resulting maximum ripple current is:

$$\Delta I_L = \frac{1.2V}{396kHz \cdot 0.56\mu H} \left(1 - \frac{1.2V}{28V} \right) = 5.1A$$

Choose the synchronous bottom MOSFET switch and calculate the V_{RNG} current limit set-point. To calculate V_{RNG} and V_{DS} , the $\rho\tau$ term normalization factor (unity at 25°C) is required to account for variation in MOSFET on-resistance with temperature. Choosing an RJK0330 ($R_{DS(ON)}$ = 2.8m Ω (nominal) 3.9m Ω (maximum), V_{GS} = 4.5V, θ_{JA} = 40°C/W) yields a drain source voltage of:

$$V_{DS} = \left(I_{LIMIT} - \frac{1}{2}(I_{RIPPLE}) \right) 3.9m\Omega (\rho\tau)$$

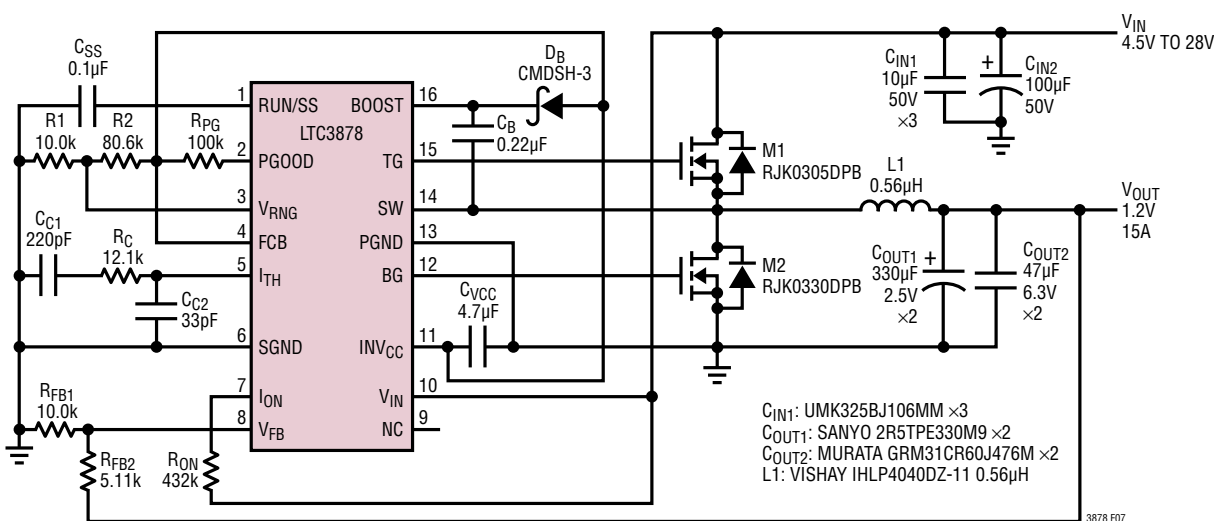

Figure 7. Design Example: 1.2V/15A at 400kHz

APPLICATIONS INFORMATION

V_{RNG} sets current limit by fixing the maximum peak V_{DS} voltage on the bottom MOSFET switch. As a result, the average DC current limit includes significant temperature and component variability. Design to guarantee that the average DC current limit will always exceed the rated operating output current by assuming worst-case component tolerance and temperature.

The worst-case minimum INTV_{CC} is 5.15V. The bottom MOSFET worst-case $R_{\text{DS(ON)}}$ is 3.9m Ω and the junction temperature is 80°C above a 70°C ambient with $\rho_{150^\circ\text{C}} = 1.5$. Set T_{ON} equal to the minimum specification of 15% low and the inductor 15% high.

By setting I_{LIMIT} equal to 15A we get 79mV for peak V_{DS} voltage which corresponds to a V_{RNG} equal to 592mV:

$$V_{\text{DS}} = \left(15\text{A} - \frac{1}{2} \cdot 5.1\text{A} \cdot \frac{0.85}{1.15} \right) \frac{3.9\text{m}\Omega}{\frac{5.15\text{V}}{5.3\text{V}}} \cdot 1.5$$

$$V_{\text{RNG}} = 7.5 \cdot V_{\text{DS}}$$

Verify that the calculated nominal T_{J} is less than the assumed worst-case T_{J} in the bottom MOSFET:

$$P_{\text{BOT}} = \frac{28\text{V} - 1.2\text{V}}{28\text{V}} (15\text{A})^2 \cdot 1.5 \cdot 3.9\text{m}\Omega = 1.25\text{W}$$

$$T_{\text{J}} = 70^\circ\text{C} + 1.25\text{W} \cdot 40^\circ\text{C/W} = 120^\circ\text{C}$$

Because the top MOSFET is on for a short time, an RJK0305DPB ($R_{\text{DS(ON)}} = 10\text{m}\Omega$ (nominal) 13m Ω (maximum) ($C_{\text{MILLER}} = Q_{\text{GD}}/10\text{V} = 150\text{pF}$, $V_{\text{BOOST}} = 5\text{V}$), $V_{\text{GS}} = 4.5\text{V}$, $V_{\text{MILLER}} = 3\text{V}$, $\theta_{\text{JA}} = 40^\circ\text{C/W}$) is sufficient. Checking its power dissipation at current limit with $\rho_{100^\circ\text{C}} = 1.4$:

$$P_{\text{TOP}} = \frac{1.2\text{V}}{28\text{V}} (15\text{A})^2 \cdot 1.4 \cdot 13\text{m}\Omega + (28\text{V})^2 \left(\frac{15\text{A}}{2} \right)$$

$$(150\text{pF}) \left(\frac{2.5\Omega}{5\text{V} - 3\text{V}} + \frac{1.2\Omega}{3\text{V}} \right) 400\text{kHz}$$

$$= 0.18\text{W} + 0.58\text{W} = 0.65\text{W}$$

$$T_{\text{J}} = 70^\circ\text{C} + 0.65\text{W} \cdot 40^\circ\text{C/W} = 96^\circ\text{C}$$

The junction temperatures will be significantly less at nominal current, but this analysis shows that careful attention to heat sinking will be necessary.

Select C_{IN} to give an RMS current rating greater than 4A at 85°C. The output capacitor C_{OUT1} is chosen for a low ESR of 4.5m Ω to minimize output voltage changes due to inductor ripple current and load steps. The output voltage ripple is given as:

$$\begin{aligned} \Delta V_{\text{OUT(RIPPLE)}} &= \Delta I_{\text{L(MAX)}} (\text{ESR}) \\ &= 5.1 \cdot 4.5\text{m}\Omega = 23\text{mV} \end{aligned}$$

However, a 0A to 10A load step will cause an output change of up to:

$$\begin{aligned} \Delta V_{\text{OUT(STEP)}} &= \Delta I_{\text{LOAD}} (\text{ESR}) \\ &= 10\text{A} \cdot 4.5\text{m}\Omega = 45\text{mV} \end{aligned}$$

Optional $2 \times 47\mu\text{F}$ ceramic output capacitors are included to minimize the effect of ESR and ESL in the output ripple and to improve load step response.

PC Board Layout Checklist

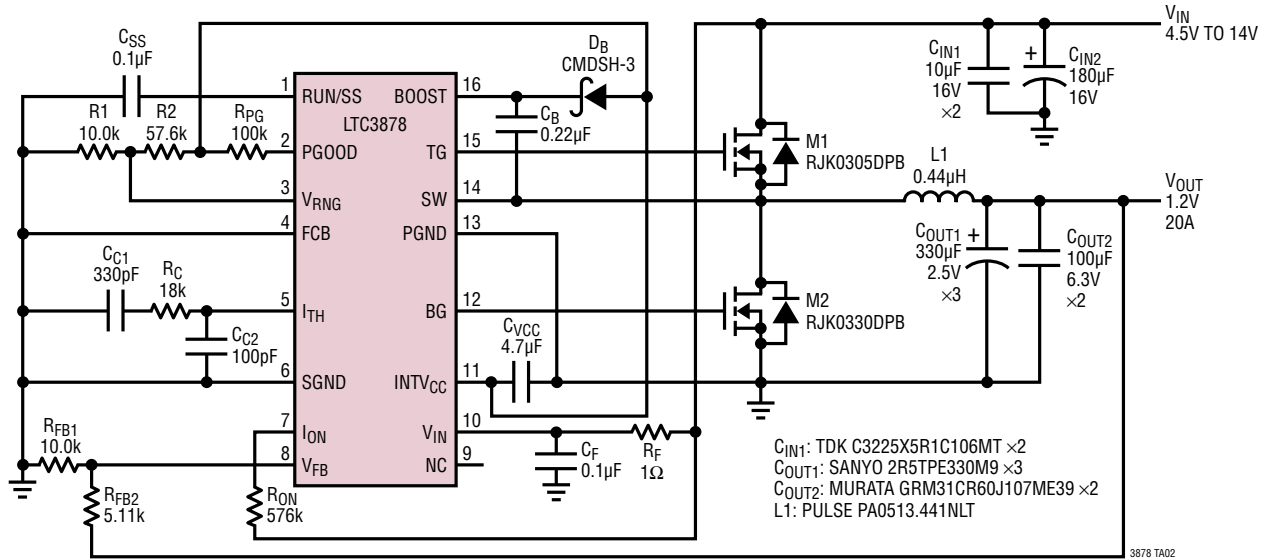

The LTC3878 PC board layout can be designed with or without a ground plane. A ground plane is generally preferred based on performance and noise concerns.

When using a ground plane, use a dedicated ground plane layer. In addition, for high current it is recommended to use a multilayer board to help with heat sinking power components.

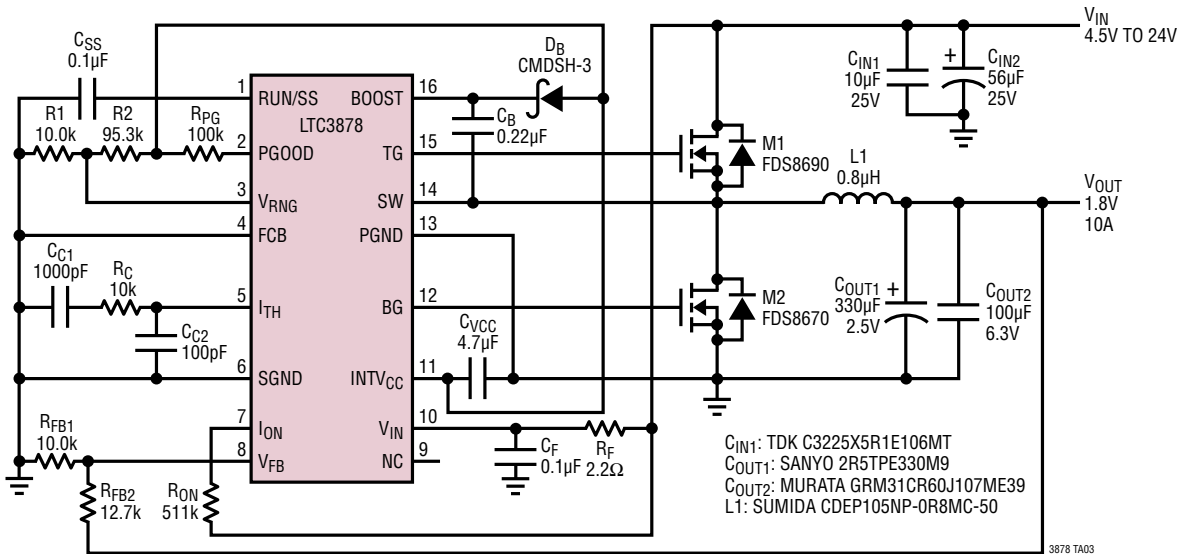

- The ground plane layer should have no traces and be as close as possible to the routing layer connecting the power MOSFET's.
- Place LTC3878 Pins 9 to 16 facing the power components. Keep components connected to Pin 1 close to LTC3878 (noise sensitive components).
- Place C_{IN} , C_{OUT} , MOSFETs, D_{B} and inductor all in one compact area. It may help to have some components on the bottom side of the board.
- Use an immediate via to connect components to the ground plane SGND and PGND of LTC3878. Use several larger vias for power components.
- Use compact switch node (SW) plane to improve cooling of the MOSFETs and to keep EMI down.

TYPICAL APPLICATIONS

4.5V to 14V Input, 1.2V/20A Output at 300kHz

4.5V to 24V Input, 1.8V/10A Output at 500kHz

TYPICAL APPLICATIONS

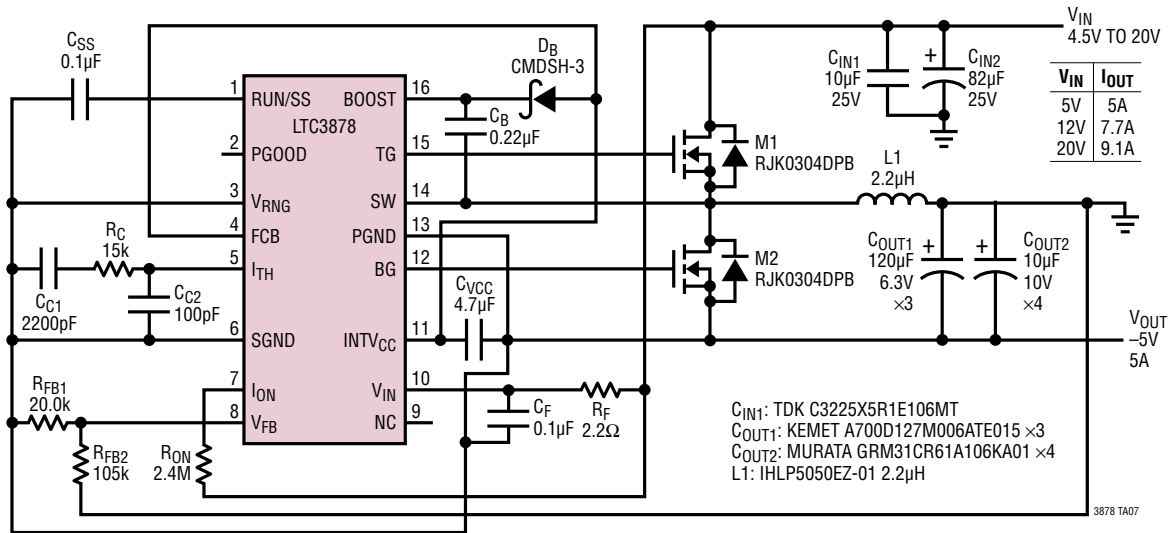

13V to 32V Input, 12V/5A Output at 300kHz

3878 TA06

TYPICAL APPLICATIONS

Positive-to-Negative Converter, -5V/5A at 300kHz

PACKAGE DESCRIPTION

GN Package 16-Lead Plastic SSOP (Narrow .150 Inch) (Reference LTC DWG # 05-08-1641)

NOTE:

1. CONTROLLING DIMENSION: INCHES
2. DIMENSIONS ARE IN $\frac{\text{INCHES}}{\text{MILLIMETERS}}$
3. DRAWING NOT TO SCALE

*DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE

**DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE
