# 1MHz, 20 $\mu$ A, Rail-to-Rail I/O Op Amps with Shutdown

## **Absolute Maximum Ratings**

Power-Supply Voltage (V <sub>DD</sub> to V <sub>SS</sub> )	0.3V to +6.0V
IN_+, IN, OUT_, SHDN(V <sub>SS</sub> - 0.3	3V) to (V <sub>DD</sub> + 0.3V)
Current into IN_+, IN	±20mA
Output Short-Circuit Duration to VDD or VSS	Continuous
Continuous Power Dissipation ( $T_A = +70^{\circ}C$ )	

5-Pin SC70 (derate 3.1mW/°C above +70°C).....247mW 6-Pin SC70 (derate 3.1mW/°C above +70°C).....245mW

8-Pin SOT23 (derate 5.1mW/°C above +	-70°C)408mW
10-Pin µMAX (derate 5.6mW/°C above -	+70°C)444mW
Operating Temperature Range	40°C to +85°C
Junction Temperature	+150°C
Storage Temperature Range	65°C to +150°C
Lead Temperature (soldering, 10s)	+300°C
Soldering Temperature (reflow)	+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### **Detailed Description**

Featuring a maximized ratio of gain bandwidth to supply current, low operating supply voltage, low input bias current, and rail-to-rail inputs and outputs, the MAX9914–MAX9917 are an excellent choice for precision or general-purpose low-current, low-voltage, battery-powered applications. These CMOS devices consume an ultra-low  $20\mu A$  (typ) supply current and a  $200\mu V$  (typ) offset voltage. For additional power conservation, the MAX9914/MAX9917 feature a lowpower shutdown mode that reduces supply current to 1nA (typ), and puts the amplifiers' output in a highimpedance state. These devices are unity-gain stable with a 1MHz gain-bandwidth product driving capacitive loads up to 30pF. The capacitive load can be increased to 100pF when the amplifier is configured for a 10V/V gain.

#### **Rail-to-Rail Inputs and Outputs**

The MAX9914–MAX9917 amplifiers all have a parallelconnected n- and p-channel differential input stage that allows an input common-mode voltage range that extends 100mV beyond the positive and negative supply rails, with excellent common-mode rejection. The MAX9914–MAX9917 are capable of driving the output to within 5mV of both supply rails with a 100k $\Omega$  load. These devices can drive a 5k $\Omega$  load with swings to within 60mV of the rails. Figure 1 shows no clipping at the output voltage swing of the MAX9914–MAX9917 configured as a unity-gain buffer powered from a single 3V supply.

#### Low Input Bias Current

The MAX9914–MAX9917 feature ultra-low 1pA (typ) input bias current. The variation in the input bias current is minimal with changes in the input voltage due to very high input impedance (in the order of  $1G\Omega$ ).

### **Applications Information**

#### **Driving Capacitive Loads**

The MAX9914–MAX9917 amplifiers are unity-gain stable for loads up to 30pF. However, the capacitive load can be increased to 100pF when the amplifier is configured for a minimum gain of 10V/V.

Applications that require greater capacitive drive capability should use an isolation resistor between the output and the capacitive load (Figure 2). Also, in unity-gain applications with relatively small R<sub>L</sub> (about 5k $\Omega$ ), the capacitive load can be increased up to 100pF.

# 1MHz, 20µA, Rail-to-Rail I/O Op Amps with Shutdown

#### **Power-Supply Considerations**

The MAX9914–MAX9917 are optimized for single 1.8V to 5.5V supply operation. A high amplifier power-supply rejection ratio of 85dB (typ) allows the devices to be powered directly from a battery, simplifying design and extending battery life.

#### **Power-Up Settling Time**

The MAX9914–MAX9917 typically require 2µs after power-up. Supply settling time depends on the supply voltage, the value of the bypass capacitor, the output impedance of the incoming supply, and any lead resistance or inductance between components. Op amp settling time depends primarily on the output voltage and is slew-rate limited. Figure 3 shows the MAX991\_ in a noninverting voltage follower configuration with the input held at midsupply. The output settles in approximately 3.5µs for V<sub>DD</sub> = 3V (see the *Typical Operating Characteristics* for the Power-Up Settling Time graph).

#### Shutdown Mode

The MAX9915 and MAX9917 feature active-low shutdown inputs. The MAX9915 and MAX9917 enter shutdown in 2µs (typ) and exit shutdown in 10µs (typ). The amplifiers' outputs are high impedance in shutdown mode. Drive SHDN low to enter shutdown. Drive SHDN high to enable the amplifier. The MAX9917 dual amplifier features separate shutdown inputs. Shut down both amplifiers for lowest quiescent current.

#### **Power-Supply Bypassing and Layout**

Bypass  $V_{DD}$  with a  $0.1 \mu F$  capacitor to ground as close to the pin as possible to minimize noise.

Good layout techniques optimize performance by decreasing the amount of stray capacitance and inductance to the op amp's inputs and outputs. Minimize stray capacitance and inductance, by placing external components close to the IC.
