	PDBUF Low @ 100 kSPS		31		mW
TEMPERATURE RANGE ⁹					
Specified Performance	T_{MIN} to T_{MAX}	−40		+85	°C

¹ See the Analog Inputs section.

² LSB means Least Significant Bit. With the ±4.096 V input range, 1 LSB is 31.25 μV.

³ See the Definition of Specifications section. The nominal gain error is not centered at zero and is −0.029% of FSR. This specification is the deviation from this nominal value. These specifications do not include the error contribution from the external reference, but do include the error contribution from the reference buffer if used.

⁴ All specifications in dB are referred to a full-scale input, FS. Tested with an input signal at 0.5 dB below full scale, unless otherwise specified.

⁵ Data format parallel or serial 18-bit.

⁶ Conversion results are available immediately after completed conversion.

⁷ The maximum should be the minimum of 5.25 V and DVDD + 0.3 V.

⁸ Tested in Parallel Reading mode.

⁹ Contact factory for extended temperature range.

TIMING SPECIFICATIONS

Table 3. -40°C to +85°C, AVDD = DVDD = 5 V, OVDD = 2.7 V to 5.25 V, unless otherwise noted.

Parameter	Symbol	Min	Typ	Max	Unit
Refer to Figure 27 and Figure 28					
Convert Pulse Width	t ₁	10			ns
Time between Conversions	t ₂	10			μs

SDOUT Valid Setup Time Minimum	t ₂₂	4	18	18	18	ns
SDOUT Valid Hold Time Minimum	t ₂₃	2	4	30	89	ns
SCLK Last Edge to SYNC Delay Minimum	t ₂₄	3	60	140	300	ns
Busy High Width Maximum	t ₂₈	2.25	3	4.5	7.5	μs

ABSOLUTE MAXIMUM RATINGS

Table 5. AD7678 Absolute Maximum Ratings¹

Parameter	Rating
Analog Inputs IN ⁺ ² , IN ⁻ ² , REF, REFBUFIN, REFGND to AGND	AVDD + 0.3 V to AGND – 0.3 V
Ground Voltage Differences AGND, DGND, OGND	±0.3 V
Supply Voltages	
AVDD, DVDD, OVDD	–0.3 V to +7 V
AVDD to DVDD, AVDD to OVDD	±7 V
DVDD to OVDD	–0.3 V to +7 V
Digital Inputs	–0.3 V to DVDD + 0.3 V
Internal Power Dissipation ³	700 mW
Internal Power Dissipation ⁴	2.5 W
Junction Temperature	150°C
Storage Temperature Range	–65°C to +150°C
Lead Temperature Range (Soldering 10 sec)	300°C

¹Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

²See Analog Inputs section.

³Specification is for device in free air: 48-Lead LQFP: $\theta_{JA} = 91^{\circ}\text{C/W}$, $\theta_{JC} = 30^{\circ}\text{C/W}$.

⁴ Specification is for device in free air: 48-Lead LFCSP: $\theta_{JA} = 26^{\circ}\text{C/W}$.

¹IN SERIAL INTERFACE MODES, THE SYNC, SCLK, AND SDOUT TIMINGS ARE DEFINED WITH A MAXIMUM LOAD C_L OF 10pF; OTHERWISE, THE LOAD IS 60pF MAXIMUM.

03084–0–002

03084–0–003

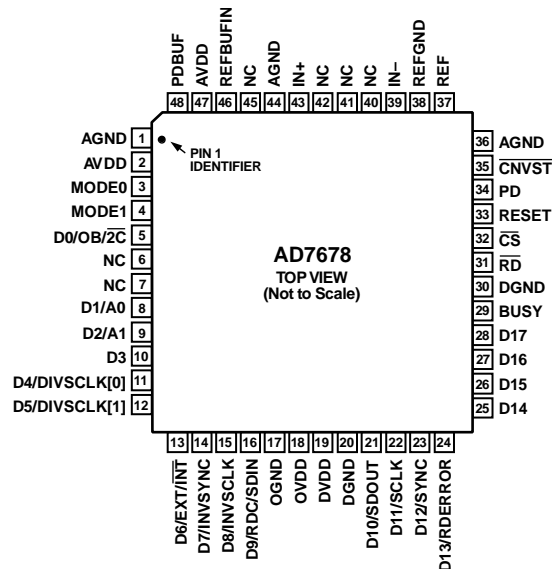

Figure 3. Voltage Reference Levels for Timing

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

1. NC = NO CONNECT.
2. THE EXPOSED PAD IS INTERNALLY CONNECTED TO AGND. THIS CONNECTION IS NOT REQUIRED TO MEET THE ELECTRICAL PERFORMANCES; HOWEVER, FOR INCREASED RELIABILITY OF THE SOLDER JOINTS, IT IS RECOMMENDED THAT THE PAD BE SOLDERED TO THE ANALOG GROUND OF THE SYSTEM.

03084-004

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Type ¹	Description																				
1, 44	AGND	P	Analog Power Ground Pin.																				
2, 47	AVDD	P	Input Analog Power Pins. Nominally 5 V.																				
3	MODE0	DI	Data Output Interface Mode Selection.																				
4	MODE1	DI	Data Output Interface Mode Selection:																				
<table border="1"> <thead> <tr> <th>Interface MODE #</th><th>MODE1</th><th>MODE0</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>0</td><td>18-Bit Interface</td></tr> <tr> <td>1</td><td>0</td><td>1</td><td>16-Bit Interface</td></tr> <tr> <td>2</td><td>1</td><td>0</td><td>Byte Interface</td></tr> <tr> <td>3</td><td>1</td><td>1</td><td>Serial Interface</td></tr> </tbody> </table>				Interface MODE #	MODE1	MODE0	Description	0	0	0	18-Bit Interface	1	0	1	16-Bit Interface	2	1	0	Byte Interface	3	1	1	Serial Interface
Interface MODE #	MODE1	MODE0	Description																				
0	0	0	18-Bit Interface																				
1	0	1	16-Bit Interface																				
2	1	0	Byte Interface																				
3	1	1	Serial Interface																				
5	D0/OB/ $\overline{2C}$	DI/O	When MODE = 0 (18-bit interface mode), this pin is Bit 0 of the parallel port data output bus and the data coding is straight binary. In all other modes, this pin allows choice of straight binary/binary twos complement. When OB/ $\overline{2C}$ is HIGH, the digital output is straight binary; when LOW, the MSB is inverted, resulting in a twos complement output from its internal shift register.																				
6, 7, 40–42, 45	NC		No Connect.																				
8	D1/A0	DI/O	When MODE = 0 (18-bit interface mode), this pin is Bit 1 of the parallel port data output bus. In all other modes, this input pin controls the form in which data is output, as shown in Table 7.																				
9	D2/A1	DI/O	When MODE = 0 or 1 (18-bit or 16-bit interface mode), this pin is Bit 2 of the parallel port data output bus. In all other modes, this input pin controls the form in which data is output, as shown in Table 7.																				
10	D3	DO	In all modes except MODE = 3, this output is used as Bit 3 of the parallel port data output bus. This pin is always an output, regardless of the interface mode.																				
11, 12	D[4:5] or DIVSCLK[0:1]	DI/O	In all modes except MODE = 3, these pins are Bit 4 and Bit 5 of the parallel port data output bus. When MODE = 3 (serial mode), EXT/ \overline{INT} is LOW, and RDC/SDIN is LOW (serial master read after convert), these inputs, part of the serial port, are used to slow down, if desired, the internal serial clock that clocks the data output. In other serial modes, these pins are not used.																				

Pin No.	Mnemonic	Type ¹	Description
13	D6 or EXT/ $\overline{\text{INT}}$	DI/O	In all modes except MODE = 3, this output is used as Bit 6 of the parallel port data output bus. When MODE = 3 (serial mode), this input, part of the serial port, is used as a digital select input for choosing the internal data clock or an external data clock. With EXT/ $\overline{\text{INT}}$ tied LOW, the internal clock is selected on the SCLK output. With EXT/ $\overline{\text{INT}}$ set to a logic HIGH, output data is synchronized to an external clock signal connected to the SCLK input.
14	D7 or INVS $\overline{\text{SYNC}}$	DI/O	In all modes except MODE = 3, this output is used as Bit 7 of the parallel port data output bus. When MODE = 3 (serial mode), this input, part of the serial port, is used to select the active state of the SYNC signal. When LOW, SYNC is active HIGH. When HIGH, SYNC is active LOW.
15	D8 or INV $\overline{\text{SCLK}}$	DI/O	In all modes except MODE = 3, this output is used as Bit 8 of the parallel port data output bus. When MODE = 3 (serial mode), this input, part of the serial port, is used to invert the SCLK signal. It is active in both master and slave modes.
16	D9 or RDC/SDIN	DI/O	In all modes except MODE = 3, this output is used as Bit 9 of the parallel port data output bus. When MODE = 3 (serial mode), this input, part of the serial port, is used as either an external data input or a read mode selection input depending on the state of EXT/ $\overline{\text{INT}}$. When EXT/ $\overline{\text{INT}}$ is HIGH, RDC/SDIN could be used as a data input to daisy-chain the conversion results from two or more ADCs onto a single SDO $\overline{\text{UT}}$ line. The digital data level on SDIN is output on SDO $\overline{\text{UT}}$ with a delay of 18 SCLK periods after the initiation of the read sequence. When EXT/ $\overline{\text{INT}}$ is LOW, RDC/SDIN is used to select the read mode. When RDC/SDIN is HIGH, the data is output on SDO $\overline{\text{UT}}$ during conversion. When RDC/SDIN is LOW, the data can be output on SDO $\overline{\text{UT}}$ only when the conversion is complete.
17	OGND	P	Input/Output Interface Digital Power Ground.
18	OVDD	P	Output Interface Digital Power. Nominally at the same supply as the host interface (5 V or 3 V). Should not exceed DVDD by more than 0.3 V.
19	DVDD	P	Digital Power. Nominally at 5 V.
20	DGND	P	Digital Power Ground.
21	D10 or SDO $\overline{\text{UT}}$	DO	In all modes except MODE = 3, this output is used as Bit 10 of the parallel port data output bus. When MODE = 3 (serial mode), this output, part of the serial port, is used as a serial data output synchronized to SCLK. Conversion results are stored in an on-chip register. The AD7678 provides the conversion result, MSB first, from its internal shift register. The data format is determined by the logic level of OB/ $\overline{2C}$. In serial mode when EXT/ $\overline{\text{INT}}$ is LOW, SDO $\overline{\text{UT}}$ is valid on both edges of SCLK. In serial mode when EXT/ $\overline{\text{INT}}$ is HIGH and INV $\overline{\text{SCLK}}$ is LOW, SDO $\overline{\text{UT}}$ is updated on the SCLK rising edge and is valid on the next falling edge; if INV $\overline{\text{SCLK}}$ is HIGH, SDO $\overline{\text{UT}}$ is updated on the SCLK falling edge and is valid on the next rising edge.
22	D11 or SCLK	DI/O	In all modes except MODE = 3, this output is used as Bit 11 of the parallel port data output bus. When MODE = 3 (serial mode), this pin, part of the serial port, is used as a serial data clock input or output, depending upon the logic state of the EXT/ $\overline{\text{INT}}$ pin. The active edge where the data SDO $\overline{\text{UT}}$ is updated depends upon the logic state of the INV $\overline{\text{SCLK}}$ pin.
23	D12 or SYNC	DO	In all modes except MODE = 3, this output is used as Bit 12 of the parallel port data output bus. When MODE = 3 (serial mode), this output, part of the serial port, is used as a digital output frame synchronization for use with the internal data clock (EXT/ $\overline{\text{INT}}$ = Logic LOW). When a read sequence is initiated and INV $\overline{\text{SYNC}}$ is LOW, SYNC is driven HIGH and remains HIGH while the SDO $\overline{\text{UT}}$ output is valid. When a read sequence is initiated and INV $\overline{\text{SYNC}}$ is HIGH, SYNC is driven LOW and remains LOW while SDO $\overline{\text{UT}}$ output is valid.
24	D13 or RD $\overline{\text{ERROR}}$	DO	In all modes except MODE = 3, this output is used as Bit 13 of the parallel port data output bus. In MODE = 3 (serial mode) and when EXT/ $\overline{\text{INT}}$ is HIGH, this output, part of the serial port, is used as an incomplete read error flag. In slave mode, when a data read is started and not complete when the following conversion is complete, the current data is lost and RD $\overline{\text{ERROR}}$ is pulsed high.
25–28	D[14:17]	DO	Bit 14 to Bit 17 of the Parallel Port Data Output Bus. These pins are always outputs regardless of the interface mode.
29	BUSY	DO	Busy Output. Transitions HIGH when a conversion is started. Remains HIGH until the conversion is complete and the data is latched into the on-chip shift register. The falling edge of BUSY could be used as a data ready clock signal.
30	DGND	P	Must Be Tied to Digital Ground.
31	$\overline{\text{RD}}$	DI	Read Data. When $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are both LOW, the interface parallel or serial output bus is enabled.
32	$\overline{\text{CS}}$	DI	Chip Select. When $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are both LOW, the interface parallel or serial output bus is enabled. $\overline{\text{CS}}$ is also used to gate the external clock.
33	RESET	DI	Reset Input. When set to a logic HIGH, reset the AD7678. Current conversion, if any, is aborted. If not used, this pin could be tied to DGND.

AD7678

Pin No.	Mnemonic	Type ¹	Description
34	PD	DI	Power-Down Input. When set to a logic HIGH, power consumption is reduced and conversions are inhibited after the current one is completed.
35	$\overline{\text{CNVST}}$	DI	Start Conversion. If $\overline{\text{CNVST}}$ is held HIGH when the acquisition phase (t_s) is complete, the next falling edge on $\overline{\text{CNVST}}$ puts the internal sample/hold into the hold state and initiates a conversion. If $\overline{\text{CNVST}}$ is held LOW when the acquisition phase is complete, the internal sample/hold is put into the hold state and a conversion is started immediately.
36	AGND	P	Must Be Tied to Analog Ground.
37	REF	AI	Reference Input Voltage and Internal Reference Buffer Output. Apply an external reference on this pin if the internal reference buffer is not used. Should be decoupled effectively with or without the internal buffer.
38	REFGND	AI	Reference Input Analog Ground.
39	IN-	AI	Differential Negative Analog Input.
43	IN+	AI	Differential Positive Analog Input.
46	REFBUFIN	AI	Reference Buffer Input Voltage. The internal reference buffer has a fixed gain. It outputs 4.096 V typically when 2.5 V is applied on this pin.
48	PDBUF	DI	Allows Choice of Buffering Reference. When LOW, buffer is selected. When HIGH, buffer is switched off.
49 (EPAD)	Exposed Pad (EPAD)		The exposed pad is internally connected to AGND. This connection is not required to meet the electrical performances; however, for increased reliability of the solder joints, it is recommended that the pad be soldered to the analog ground of the system.

¹AI = Analog Input; AO = Analog Output; DI = Digital Input; DI/O = Bidirectional Digital; DO = Digital Output; P = Power.

R[0:17] is the 18-bit ADC value stored in its output register.

DEFINITION OF SPECIFICATIONS

Integral Nonlinearity Error (INL)

Linearity error refers to the deviation of each individual code from a line drawn from negative full scale through positive full scale. The point used as negative full scale occurs $\frac{1}{2}$ LSB before the first code transition. Positive full scale is defined as a level $1\frac{1}{2}$ LSB beyond the last code transition. The deviation is measured from the middle of each code to the true straight line.

Differential Nonlinearity Error (DNL)

In an ideal ADC, code transitions are 1 LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

Gain Error

The first transition (from 000...00 to 000...01) should occur for an analog voltage $\frac{1}{2}$ LSB above the nominal –full scale (–4.095991 V for the ± 4.096 V range). The last transition (from 111...10 to 111...11) should occur for an analog voltage $1\frac{1}{2}$ LSB below the nominal full scale (4.095977 V for the ± 4.096 V range). The gain error is the deviation of the difference between the actual level of the last transition and the actual level of the first transition from the difference between the ideal levels.

Zero Error

The zero error is the difference between the ideal midscale input voltage (0 V) from the actual voltage producing the midscale output code.

Spurious-Free Dynamic Range (SFDR)

SFDR is the difference, in decibels (dB), between the rms amplitude of the input signal and the peak spurious signal.

Effective Number of Bits (ENOB)

ENOB is a measurement of the resolution with a sine wave input, and is expressed in bits. It is related to $S/(N+D)$ by the following formula:

$$ENOB = (S/[N+D]dB - 1.76)/6.02$$

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal, and is expressed in decibels.

Dynamic Range

Dynamic range is the ratio of the rms value of the full scale to the rms noise measured with the inputs shorted together. The value for dynamic range is expressed in decibels.

Signal-to-Noise Ratio (SNR)

SNR is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels.

Signal-to-(Noise + Distortion) Ratio ($S/(N+D)$)

$S/(N+D)$ is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for $S/(N+D)$ is expressed in decibels.

Aperture Delay

Aperture delay is a measure of the acquisition performance and is measured from the falling edge of the CNVST input to when the input signal is held for a conversion.

Transient Response

Transient response is the time required for the AD7678 to achieve its rated accuracy after a full-scale step function is applied to its input.

CIRCUIT INFORMATION

Figure 19. ADC Simplified Schematic

The AD7678 is a very fast, low power, single-supply, precise 18-bit analog-to-digital converter (ADC) using successive approximation architecture.

The AD7678's linearity and dynamic range are similar or better than many Σ - Δ ADCs. With the advantages of its successive architecture, which ease multiplexing and reduce power with throughput, it can be advantageous in applications that normally use Σ - Δ ADCs.

The AD7678 provides the user with an on-chip track/hold, successive approximation ADC that does not exhibit any pipeline or latency, making it ideal for multiple multiplexed channel applications.

The AD7678 can be operated from a single 5 V supply and can be interfaced to either 5 V or 3 V digital logic. It is housed in a 48-lead LQFP, or a tiny 48-lead LFCSP package that offers space savings and allows for flexible configurations as either a serial or parallel interface. The AD7678 is pin-to-pin compatible with the AD7674, AD7676, and AD7679.

CONVERTER OPERATION

The AD7678 is a successive approximation ADC based on a charge redistribution DAC. Figure 19 shows the simplified schematic of the ADC. The capacitive DAC consists of two identical arrays of 18 binary weighted capacitors, which are connected to the two comparator inputs.

During the acquisition phase, terminals of the array tied to the comparator's input are connected to AGND via SW+ and SW-. All independent switches are connected to the analog inputs. Thus, the capacitor arrays are used as sampling capacitors and acquire the analog signal on IN+ and IN- inputs. When the acquisition phase is complete and the CNVST input goes low, a conversion phase is initiated. When the conversion phase begins, SW+ and SW- are opened first. The two capacitor arrays are then disconnected from the inputs and connected to the REFGND input. Therefore, the differential voltage between the IN+ and IN- inputs captured at the end of the acquisition phase is applied to the comparator inputs, causing the comparator to become unbalanced. By switching each element of the capacitor array between REFGND and REF, the comparator input varies by binary weighted voltage steps ($V_{REF}/2$, $V_{REF}/4$... $V_{REF}/262144$). The control logic toggles these switches, starting with the MSB first, to bring the comparator back into a balanced condition. After completing this process, the control logic generates the ADC output code and brings the BUSY output low.

Transfer Functions

Except in 18-bit interface mode, the AD7678 offers straight binary and twos complement output coding when using $\overline{OB}/2\overline{C}$. See Figure 20 and Table 8 for the ideal transfer characteristic.

Figure 20. ADC Ideal Transfer Function

Table 8. Output Codes and Ideal Input Voltages

Description	Analog Input $V_{REF} = 4.096 \text{ V}$	Straight Binary (Hex)	Twos Complement (Hex)
FSR - 1 LSB	4.095962 V	3FFFF ¹	1FFFF ⁵
FSR - 2 LSB	4.095924 V	3FFFE	1FFFE
Midscale + 1 LSB	31.25 μV	20001	00001
Midscale	0 V	20000	00000
Midscale - 1 LSB	-31.25 μV	1FFFF	3FFFF
-FSR + 1 LSB	-4.095962 V	00001	20001
-FSR	-4.096 V	00000 ²	20000 ⁶

¹ This is also the code for overrange analog input ($V_{IN+} - V_{IN-}$ above $V_{REF} - V_{REFGND}$).

² This is also the code for underrange analog input ($V_{IN+} - V_{IN-}$ below $-V_{REF} + V_{REFGND}$).

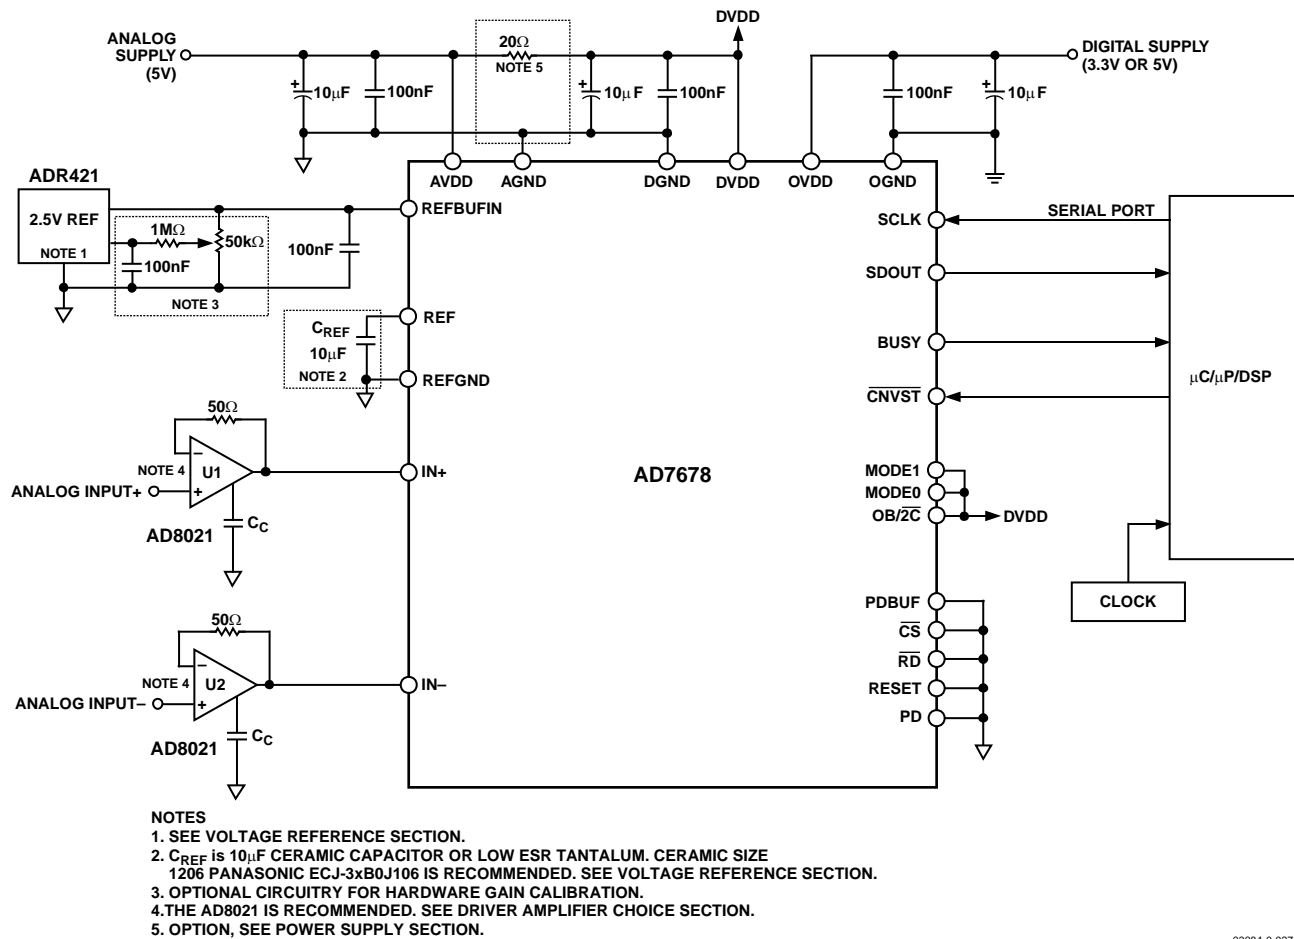

Figure 21. Typical Connection Diagram (Internal Reference Buffer, Serial Interface)

TYPICAL CONNECTION DIAGRAM

Figure 21 shows a typical connection diagram for the AD7678. Different circuitry shown on this diagram is optional and is discussed later in this data sheet.

Analog Inputs

Figure 22 shows a simplified analog input section of the AD7678. The diodes shown in Figure 22 provide ESD protection for the inputs. Care must be taken to ensure that the analog input signal never exceeds the absolute ratings on these inputs. This will cause these diodes to become forward-biased and start conducting current. These diodes can handle a forward-biased current of 120 mA max. This condition could eventually occur when the input buffer's U1 or U2 supplies are different from AVDD. In such a case, an input buffer with a short-circuit current limitation can be used to protect the part.

Figure 22. Simplified Analog Input

This analog input structure is a true differential structure. By using these differential inputs, signals common to both inputs are rejected as shown in Figure 23, which represents typical CMRR over frequency.

Figure 23. Analog Input CMRR vs. Frequency

During the acquisition phase for ac signals, the AD7678 behaves like a 1-pole RC filter consisting of the equivalent resistance, R_+ , R_- , and C_s . Resistors R_+ and R_- are typically 3 kΩ and are lumped components made up of a serial resistor and the on resistance of the switches. C_s is typically 60 pF and mainly consists of the ADC sampling capacitor. This 1-pole filter with a -3 dB cutoff frequency of 900 kHz typ reduces any undesirable aliasing effect and limits the noise coming from the inputs.

Because the input impedance of the AD7678 is very high, the part can be driven directly by a low impedance source without gain error.

Driver Amplifier Choice

Although the AD7678 is easy to drive, the driver amplifier needs to meet the following requirements:

- The driver amplifier and the AD7678 analog input circuit have to be able to settle for a full-scale step of the capacitor array at an 18-bit level (0.0004%). In the amplifier's data sheet, settling at 0.1% or 0.01% is more commonly specified. This could differ significantly from the settling time at an 18-bit level and, therefore, should be verified prior to driver selection. The tiny op amp AD8021, which combines ultralow noise and high gain-bandwidth, meets this settling time requirement.
- The noise generated by the driver amplifier needs to be kept as low as possible in order to preserve the SNR and transition noise performance of the AD7678. The noise coming from the driver is filtered by the AD7678 analog input circuit 1-pole low-pass filter made by R_+ , R_- , and C_s .

The SNR degradation due to the amplifier is

$$SNR_{LOSS} = 20 \log \left(\frac{25}{\sqrt{625 + \pi f_{-3dB} (Ne_N)^2}} \right)$$

where:

f_{-3dB} is the -3 dB input bandwidth in MHz of the AD7678 (0.9 MHz).

N is the noise factor of the amplifiers (1 if in buffer configuration).

e_N is the equivalent input noise voltage of each op amp in nV/ $\sqrt{\text{Hz}}$.

For instance, for a driver with an equivalent input noise of 6 nV/ $\sqrt{\text{Hz}}$ (e.g., AD8610) configured as a buffer, thus with a noise gain of +1, the SNR degrades by only 0.65 dB.

- The driver needs to have a THD performance suitable to that of the AD7678.

The AD8021 meets these requirements and is usually appropriate for almost all applications. The AD8021 needs a 10 pF external compensation capacitor, which should have good linearity as an NPO ceramic or mica type.

The AD8022 could be used if a dual version is needed and gain of 1 is present. The AD829 is an alternative in applications where high frequency (above 100 kHz) performance is not required. In gain of 1 applications, it requires an 82 pF compensation capacitor. The AD8610 is another option when low bias current is needed in low frequency applications.

Single-to-Differential Driver

For applications using unipolar analog signals, a single-ended-to-differential driver will allow for a differential input into the part. The schematic is shown in Figure 24. When provided an input signal of 0 to V_{REF} , this configuration will produce a differential $\pm V_{REF}$ with midscale at $V_{REF}/2$.

If the application can tolerate more noise, the AD8138 differential driver can be used.

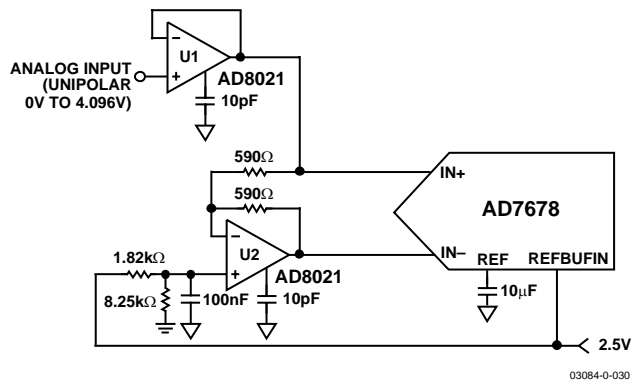

Figure 24. Single-Ended-to-Differential Driver Circuit (Internal Reference Buffer Used)

Voltage Reference

The AD7678 allows the use of an external voltage reference with or without the internal reference buffer.

Using the internal reference buffer is recommended when sharing a common reference voltage between multiple ADCs is desired.

However, the advantages of using the external reference voltage directly are

- The SNR and dynamic range improvement (about 1.7 dB) resulting from the use of a reference voltage very close to the supply (5 V) instead of a typical 4.096 V reference when the internal buffer is used.
- The power saving when the internal reference buffer is powered down (PDBUF HIGH).

To use the internal reference buffer, PDBUF should be LOW. A 2.5 V reference voltage applied on the REFBUF pin will result in a 4.096 V reference on the REF pin.

In both cases, the voltage reference input REF has a dynamic input impedance and therefore requires an efficient decoupling between REF and REFGND inputs. The decoupling consists of a low ESR 47 μF tantalum capacitor connected to the REF and REFGND inputs with minimum parasitic inductance.

Care should also be taken with the reference temperature coefficient of the voltage reference, which directly affects the full-scale accuracy if this parameter matters. For instance, a ± 4 ppm/°C temperature coefficient of the reference changes the full scale by ± 1 LSB/°C.

Power Supply

The AD7678 uses three sets of power supply pins: an analog 5 V supply (AVDD), a digital 5 V core supply (DVDD), and a digital output interface supply (OVDD). The OVDD supply defines the output logic level and allows direct interface with any logic working between 2.7 V and DVDD + 0.3 V. To reduce the number of supplies needed, the digital core (DVDD) can be supplied through a simple RC filter from the analog supply, as shown in Figure 21. The AD7678 is independent of power supply sequencing once OVDD does not exceed DVDD by more than 0.3 V, and is therefore free from supply voltage induced latch-up. Additionally, it is very insensitive to power supply variations over a wide frequency range, as shown in Figure 25.

Figure 25. PSRR vs. Frequency

POWER DISSIPATION VERSUS THROUGHPUT

The AD7678 automatically reduces its power consumption at the end of each conversion phase. During the acquisition phase, the operating currents are very low, which allows for a significant power savings when the conversion rate is reduced, as shown in Figure 26. This feature makes the AD7678 ideal for very low power battery applications.

It should be noted that the digital interface remains active even during the acquisition phase. To reduce the operating digital supply currents even further, the digital inputs need to be driven close to the power rails (DVDD and DGND), and OVDD should not exceed DVDD by more than 0.3 V.

Figure 26. Power Dissipation vs. Sample Rate

CONVERSION CONTROL

Figure 27 shows the detailed timing diagrams of the conversion process. The AD7678 is controlled by the $\overline{\text{CNVST}}$ signal, which initiates conversion. Once initiated, it cannot be restarted or aborted, even by the power-down input PD, until the conversion is complete. The $\overline{\text{CNVST}}$ signal operates independently of the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ signals.

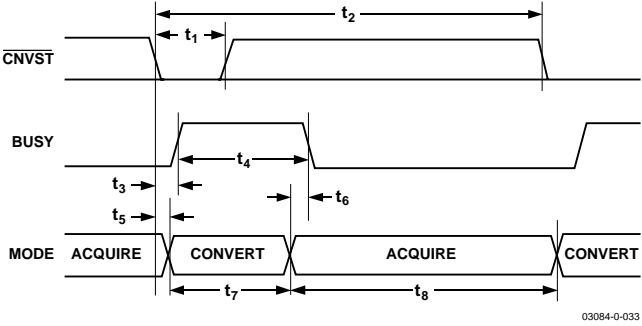

Figure 27. Basic Conversion Timing

Although $\overline{\text{CNVST}}$ is a digital signal, it should be designed with special care with fast, clean edges and levels with minimum overshoot and undershoot or ringing.

For other applications, conversions can be automatically initiated. If $\overline{\text{CNVST}}$ is held low when BUSY is low, the AD7678 controls the acquisition phase and then automatically initiates a new conversion. By keeping $\overline{\text{CNVST}}$ low, the AD7678 keeps the conversion process running by itself. It should be noted that the analog input has to be settled when BUSY goes low. Also, at power-up, $\overline{\text{CNVST}}$ should be brought low once to initiate the conversion process. In this mode, the AD7678 could sometimes run slightly faster than the guaranteed limits of 100 kSPS.

Figure 28. RESET Timing

DIGITAL INTERFACE

The AD7678 has a versatile digital interface; it can be interfaced with the host system by using either a serial or parallel interface. The serial interface is multiplexed on the parallel data bus. The AD7678 digital interface also accommodates both 3 V and 5 V logic by simply connecting the AD7678's OVDD supply pin to the host system interface digital supply. Finally, by using the OB/2C input pin in any mode except 18-bit interface mode, both twos complement and straight binary coding can be used.

The two signals, \overline{CS} and \overline{RD} , control the interface. When at least one of these signals is high, the interface outputs are in high impedance. Usually, \overline{CS} allows the selection of each AD7678 in multicircuit applications, and is held low in a single AD7678 design. \overline{RD} is generally used to enable the conversion result on the data bus.

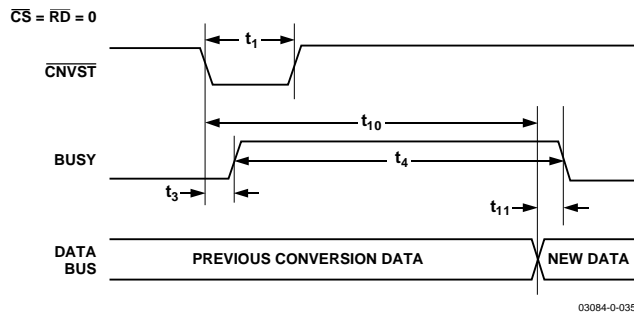

Figure 29. Master Parallel Data Timing for Reading (Continuous Read)

PARALLEL INTERFACE

The AD7678 is configured to use the parallel interface with an 18-bit, a 16-bit, or an 8-bit bus width, according to Table 7. The data can be read either after each conversion, which is during the next acquisition phase, or during the following conversion, as shown in Figure 30 and Figure 31, respectively. When the data is read during the conversion, however, it is recommended that it is read only during the first half of the conversion phase. This avoids any potential feedthrough between voltage transients on the digital interface and the most critical analog conversion circuitry. Refer to Table 7 for a detailed description of the different options available.

Figure 30. Slave Parallel Data Timing for Reading (Read after Convert)

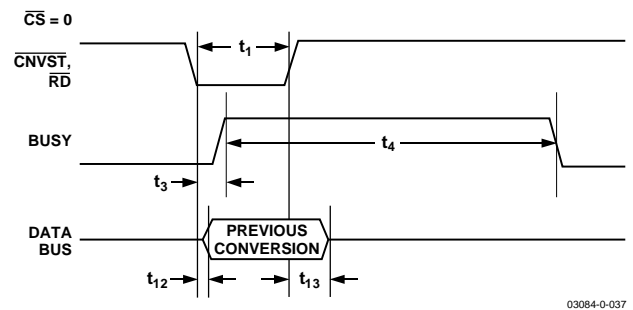

Figure 31. Slave Parallel Data Timing for Reading (Read during Convert)

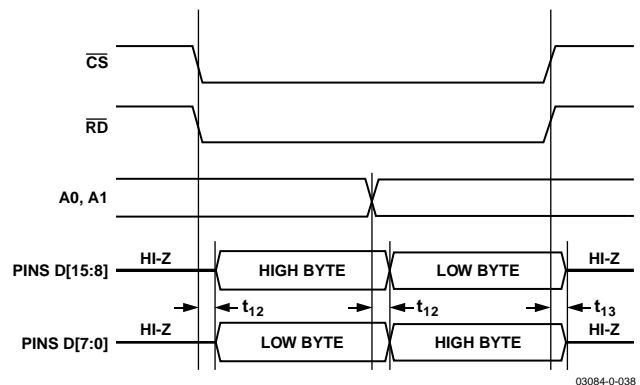

Figure 32. 8-Bit and 16-Bit Parallel Interface

SERIAL INTERFACE

The AD7678 is configured to use the serial interface when MODE0 and MODE1 are held high. The AD7678 outputs 18 bits of data, MSB first, on the SDOUT pin. This data is synchronized with the 18 clock pulses provided on the SCLK pin. The output data is valid on both the rising and falling edge of the data clock.

MASTER SERIAL INTERFACE

Internal Clock

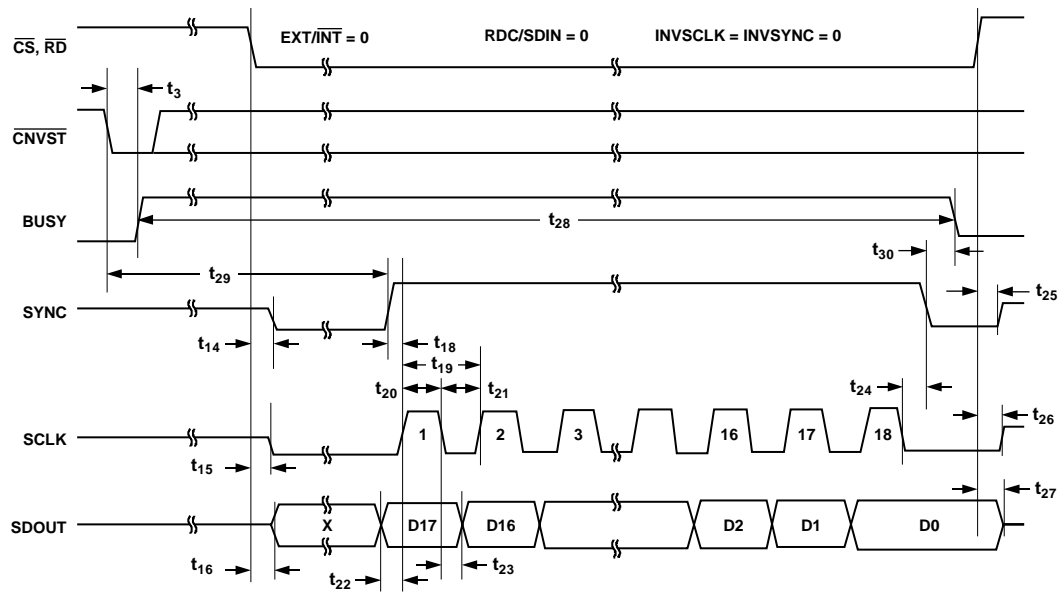

The AD7678 is configured to generate and provide the serial data clock SCLK when the EXT/INT pin is held low. The AD7678 also generates a SYNC signal to indicate to the host when the serial data is valid. The serial clock SCLK and the SYNC signal can be inverted if desired. Depending on the RDC/SDIN input, the data can be read after each conversion or during the following conversion. Figure 33 and Figure 34 show the detailed timing diagrams of these two modes.

Usually, because the AD7678 is used with a fast throughput, the mode master read during conversion is the most recommended serial mode.

In Read during Conversion mode, the serial clock and data toggle at appropriate instants, minimizing potential feedthrough between digital activity and critical conversion decisions.

In Read after Conversion mode, it should be noted that unlike in other modes, the BUSY signal returns low after the 18 data bits are pulsed out and not at the end of the conversion phase, which results in a longer BUSY width.

To accommodate slow digital hosts, the serial clock can be slowed down by using DIVSCLK.

03084-0-039

Figure 33. Master Serial Data Timing for Reading (Read after Convert)

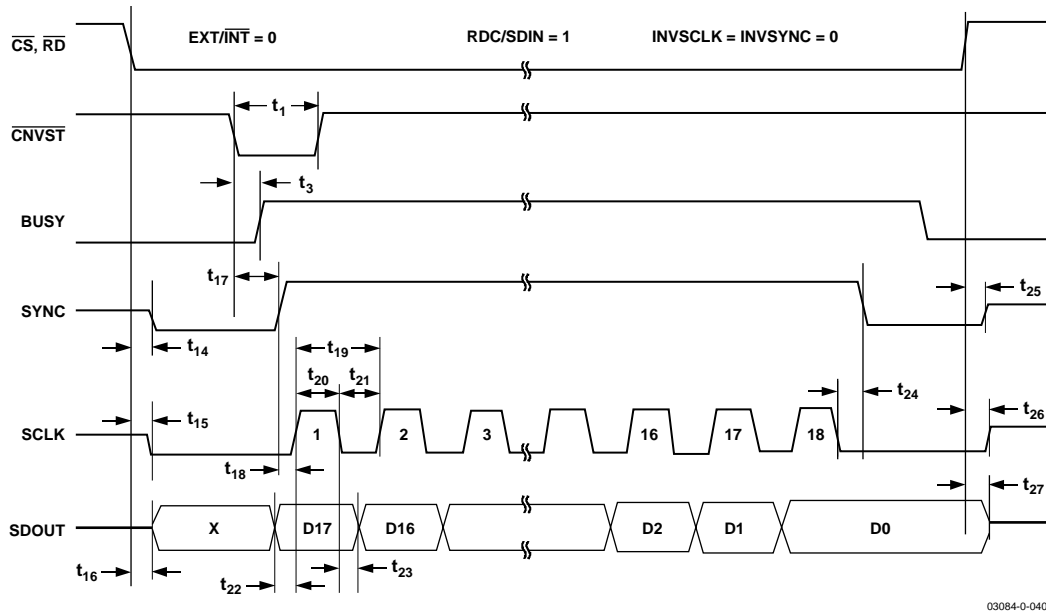

Figure 34. Master Serial Data Timing for Reading (Read Previous Conversion during Convert)

SLAVE SERIAL INTERFACE

External Clock

The AD7678 is configured to accept an externally supplied serial data clock on the SCLK pin when the EXT/INT pin is held high. In this mode, several methods can be used to read the data. The external serial clock is gated by \overline{CS} . When \overline{CS} and \overline{RD} are both low, the data can be read after each conversion or during the following conversion. The external clock can be either a continuous or a discontinuous clock. A discontinuous clock can be either normally high or normally low when inactive. Figure 35 and Figure 36 show the detailed timing diagrams of these methods.

While the AD7678 is performing a bit decision, it is important that voltage transients not occur on digital input/output pins or degradation of the conversion result could occur. This is particularly important during the second half of the conversion phase because the AD7678 provides error correction circuitry that can correct for an improper bit decision made during the first half of the conversion phase. For this reason, it is recommended that when an external clock is being provided, it is a discontinuous clock that only toggles when BUSY is low or, more importantly, that it does not transition during the latter half of BUSY high.

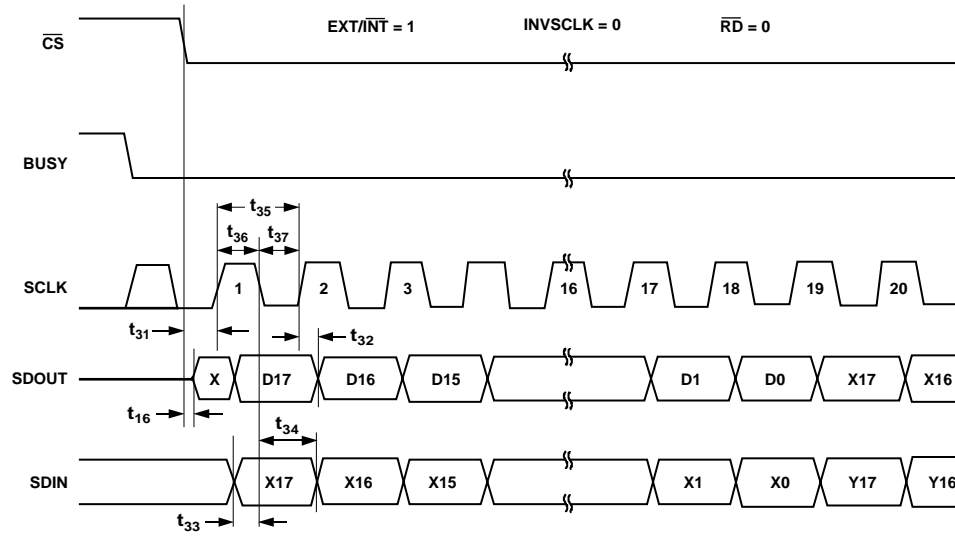

External Discontinuous Clock Data Read after Conversion

This mode is the most recommended of the serial slave modes. Figure 35 shows the detailed timing diagrams of this method. After a conversion is complete, indicated by BUSY returning low, the result of this conversion can be read while both \overline{CS} and \overline{RD} are low. Data is shifted out MSB first with 18 clock pulses, and is valid on both the rising and falling edge of the clock.

Among the advantages of this method, the conversion performance is not degraded because there are no voltage transients on the digital interface during the conversion process. Also, data can be read at speeds up to 40 MHz, accommodating both slow digital host interface and the fastest serial reading.

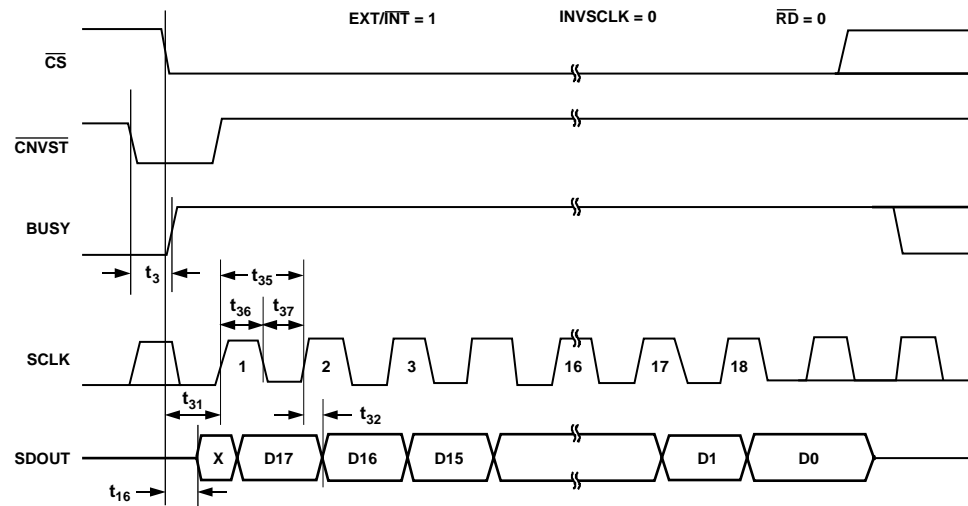

Finally, in this mode only, the AD7678 provides a daisy-chain feature using the RDC/SDIN input pin to cascade multiple converters together. This feature is useful for reducing component count and wiring connections when desired (for instance, in isolated multiconverter applications).

An example of the concatenation of two devices is shown in Figure 37. Simultaneous sampling is possible by using a common \overline{CNVST} signal. It should be noted that the RDC/SDIN input is latched on the edge of SCLK opposite the one used to shift out data on SDOUT. Thus, the MSB of the upstream converter follows the LSB of the downstream converter on the next SCLK cycle.

03084-0-041

Figure 35. Slave Serial Data Timing for Reading (Read after Convert)

03084-0-042

Figure 36. Slave Serial Data Timing for Reading (Read Previous Conversion during Convert)

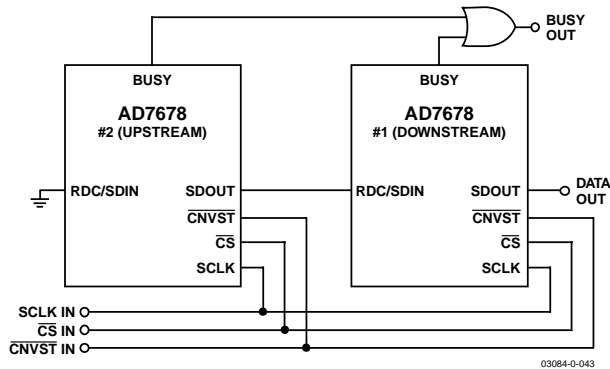

Figure 37. Two AD7678s in a Daisy-Chain Configuration

External Clock Data Read during Conversion

Figure 36 shows the detailed timing diagrams of this method. During a conversion, while both \overline{CS} and \overline{RD} are low, the result of the previous conversion can be read. The data is shifted out MSB first with 18 clock pulses, and is valid on both the rising and falling edge of the clock. The 18 bits have to be read before the current conversion is complete. If that is not done, $RDERROR$ is pulsed high and can be used to interrupt the host interface to prevent incomplete data reading. There is no daisy-chain feature in this mode, and the RDC/SDIN input should always be tied either high or low.

To reduce performance degradation due to digital activity, a fast discontinuous clock is recommended to ensure that all bits are read during the first half of the conversion phase. It is also possible to begin to read the data after conversion and continue to read the last bits even after a new conversion has been initiated.

MICROPROCESSOR INTERFACING

The AD7678 is ideally suited for traditional dc measurement applications supporting a microprocessor, and for ac signal processing applications interfacing to a digital signal processor. The AD7678 is designed to interface either with a parallel 8-bit or 16-bit wide interface, or with a general-purpose serial port or I/O ports on a microcontroller. A variety of external buffers can be used with the AD7678 to prevent digital noise from coupling into the ADC. The following section illustrates the use of the AD7678 with an SPI equipped DSP, the ADSP-219x.

SPI Interface (ADSP-219x)

Figure 38 shows an interface diagram between the AD7678 and the SPI equipped ADSP-219x. To accommodate the slower speed of the DSP, the AD7678 acts as a slave device, and data must be read after conversion. This mode also allows the daisy-chain feature. The convert command could be initiated in response to an internal timer interrupt. The 18-bit output data are read with 3-byte SPI access. The reading process could be initiated in response to the end-of-conversion signal ($BUSY$ going low) using an interrupt line of the DSP. The serial interface (SPI) on the ADSP-219x is configured for master mode ($MSTR$) = 1, Clock Polarity bit ($CPOL$) = 0, Clock Phase bit ($CPHA$) = 1, and SPI interrupt enable ($TIMOD$) = 00, by writing to the SPI control register ($SPICLTx$). It should be noted that to meet all timing requirements, the SPI clock should be limited to 17 Mbits/s, which allow it to read an ADC result in about 1.1 μ s.

Figure 38. Interfacing the AD7678 to an SPI Interface

APPLICATION HINTS

LAYOUT

The AD7678 has very good immunity to noise on the power supplies. However, care should still be taken with regard to grounding layout.

The printed circuit board that houses the AD7678 should be designed so that the analog and digital sections are separated and confined to certain areas of the board. This facilitates the use of ground planes that can be easily separated. Digital and analog ground planes should be joined in only one place, preferably underneath the AD7678, or at least as close to the AD7678 as possible. If the AD7678 is in a system where multiple devices require analog-to-digital ground connections, the connection should still be made at one point only, a star ground point that should be established as close to the AD7678 as possible.

The user should avoid running digital lines under the device, because these will couple noise onto the die. The analog ground plane should be allowed to run under the AD7678 to avoid noise coupling. Fast switching signals like $\overline{\text{CNVST}}$ or clocks should be shielded with digital ground to avoid radiating noise to other sections of the board, and should never run near analog signal paths. Crossover of digital and analog signals should be avoided. Traces on different but close layers of the board should run at right angles to each other. This will reduce the effect of feedthrough through the board. The power supply lines to the AD7678 should use as large a trace as possible to provide low impedance paths and reduce the effect of glitches on the power supply lines. Good decoupling is also important to lower the supply's impedance presented to the AD7678 and to reduce the magnitude of the supply spikes. Decoupling ceramic capacitors, typically 100 nF, should be placed close to and ideally right up against each power supply pin (AVDD, DVDD, and OVDD) and their corresponding ground pins. Additionally, low ESR 10 μF capacitors should be located near the ADC to further reduce low frequency ripple.

The DVDD supply of the AD7678 can be a separate supply or can come from the analog supply, AVDD, or the digital interface supply, OVDD. When the system digital supply is noisy or when fast switching digital signals are present, and if no separate supply is available, the user should connect the DVDD digital supply to the analog supply AVDD through an RC filter, (see Figure 21), and connect the system supply to the

interface digital supply OVDD and the remaining digital circuitry. When DVDD is powered from the system supply, it is useful to insert a bead to further reduce high frequency spikes.

The AD7678 has four different ground pins: REFGND, AGND, DGND, and OGND. REFGND senses the reference voltage and should be a low impedance return to the reference because it carries pulsed currents. AGND is the ground to which most internal ADC analog signals are referenced. This ground must be connected with the least resistance to the analog ground plane. DGND must be tied to the analog or digital ground plane depending on the configuration. OGND is connected to the digital system ground.

The layout of the decoupling of the reference voltage is important. The decoupling capacitor should be close to the ADC and should be connected with short and large traces to minimize parasitic inductances.

EVALUATING THE AD7678'S PERFORMANCE

The evaluation board for the AD7678 allows a quick means to measure both dc (histograms and time domain) and ac (time and frequency domain) performances of the converter. The EVAL-AD7678CBZ is an evaluation board package that includes a fully assembled and tested evaluation board, documentation, and software. The accompanying software requires the use of a capture board that must be ordered separately from the evaluation board (see the Ordering Guide for information). The evaluation board can also be used in a standalone configuration and does not use the software when in this mode. Refer to the [EVAL-AD76XXEDZ](#) and [EVAL-AD76XXCBZ](#) data sheets available from www.analog.com for evaluation board details.

Two types of data capture boards can be used with the EVAL-AD7678CBZ:

- USB based (EVAL-CED1Z recommended)
- Parallel port based (EVAL-CONTROL BRD3Z not recommended because many newer PCs do not include parallel ports any longer)

The recommended board layout for the AD7678 is outlined in the evaluation board data sheet.
