### PIN FUNCTIONS

**CHARGE (Pin 1):** Charge Pin. A low (<0.3V) to high (>1V) transition on this pin puts the part into power delivery mode. Once the target voltage is reached, the part will stop charging the output. Toggle this pin to start charging again. Bringing the pin low (<0.3V) will terminate the power delivery and put the part in shutdown.

**V**<sub>BAT</sub> (**Pin 2**): Battery Supply Pin. Must be locally bypassed with a good quality ceramic capacitor. Battery supply must be 1.7V or higher.

 $V_{IN}$  (Pin 3): Input Supply Pin. Must be locally bypassed with a good quality ceramic capacitor. Input supply must be 2.5V or higher.

**SW (Pins 4, 5):** Switch Pin. This is the collector of the internal NPN power switch. Minimize the metal trace area connected to this pin to minimize EMI. Tie one side of the primary of the transformer to this pin. The target output voltage is set by the turns ratio of the transformer.

Choose Turns Ratio N by the following equation:

$$\mathsf{N} = \frac{\mathsf{V}_{\mathsf{OUT}} + 2}{31.5}$$

where  $V_{OUT}$  is the desired output voltage.

**IGBTOUT (Pin 6):** Output Drive for IGBT Gate. Connect this pin to the gate of the IGBT.

**IGBTIN (Pin 7):** Logic Input Pin for IGBT Drive. When this pin is driven higher than 1.5V, the IGBT output pin goes high. When the pin is below 0.3V, the output is low.

**IGBTPWR (Pin 8):** Input Supply Pin. Must be locally bypassed with a good quality ceramic capacitor. Input supply must be 0.1V higher than the turn-on voltage for the IGBT.

**DONE** (Pin 9): Open NPN Collector Indication Pin. When target output voltage is reached, NPN turns on. This pin needs a pull-up resistor or current source.

**V**<sub>MONT</sub> (**Pin 10**): Supplies a voltage proportional to the output voltage where 1V is the end of charge voltage. Only valid while the part is charging.

**Exposed Pad (Pin 11):** Ground. Tie directly to local ground plane.

### FUNCTIONAL BLOCK DIAGRAM

Figure 1

### OPERATION

The LT3485-0/LT3485-1/LT3485-2/LT3485-3 are designed to charge photoflash capacitors quickly and efficiently. The operation of the part can be best understood by referring to Figure 1. When the CHARGE pin is first driven high, a one shot sets both SR latches in the correct state. The power NPN device, Q1, turns on and current begins ramping up in the primary of transformer T1. Comparator A1 monitors the switch current and when the peak current reaches 2A (LT3485-3), 1.4A (LT3485-0), 1A (LT3485-2) or 0.7A (LT3485-1), Q1 is turned off. Since T1 is utilized as a flyback transformer, the flyback pulse on the SW pin will cause the output of A3 to be high. The voltage on the SW pin needs to be at least 45mV higher than V<sub>BAT</sub> for this to happen.

During this phase, current is delivered to the photoflash capacitor via the secondary and diode D1. As the secondary current decreases to zero, the SW pin voltage will begin to collapse. When the SW pin voltage drops to 45mV above V<sub>BAT</sub> or lower, the output of A3 (DCM Comparator) will go low. This fires a one shot which turns Q1 back on. This cycle will continue to deliver power to the output.

Output voltage detection is accomplished via R2, R1, Q2, and comparator A2 ( $V_{OUT}$  Comparator). Resistors R1 and R2 are sized so that when the SW voltage is 31.5V above  $V_{BAT}$ , the output of A2 goes high which resets the master latch. This disables Q1 and halts power delivery. NPN transistor Q3 is turned on pulling the DONE pin low, indicating that the part has finished charging. Power delivery can only be restarted by toggling the CHARGE pin.

The CHARGE pin gives full control of the part to the user. The charging can be halted at any time by bringing the CHARGE pin low. Only when the final output voltage is reached will the DONE pin go low. Figure 2 shows these various modes in action. When CHARGE is first brought high, charging commences. When CHARGE is brought low during charging, the part goes into shutdown and  $V_{OUT}$  no longer rises. When CHARGE is brought high again, charging resumes. When the target  $V_{OUT}$  voltage is reached, the DONE pin goes low and charging stops. Finally the CHARGE pin is brought low again so the part enters shutdown and the DONE pin goes high.

Both  $V_{BAT}$  and  $V_{IN}$  have undervoltage lockout (UVLO). When one of these pins goes below its UVLO voltage, the DONE pin goes low. With an insufficient bypass capacitor on  $V_{BAT}$  or  $V_{IN}$ , the ripple on the pin is likely to activate UVLO and terminate the charge. The applications circuits in the data sheet suggest values adequate for most applications.

The LT3485  $V_{MONT}$  pin functions as an output to a microcontroller to communicate the progress of the charge. The  $V_{MONT}$  pin starts to function at about 0.2V, which corresponds to 64V with a <u>turns</u> ratio of 10.2. When the  $V_{MONT}$  pin is at 1V, the DONE pin goes low and the charging terminates. The pin's output is only valid when the part is charging.

The LT3485 also integrates an IGBT drive. The IGBTPWR pin supplies the power. The IGBT output goes high when IGBTIN goes high and conversely goes low when IGBTIN goes low. While IGBTIN is low, the IGBT drive draws no quiescent current from IGBTPWR.

Figure 2. Halting the Charging Cycle with the CHARGE Pin

#### Choosing the Right Device (LT3485-0/LT3485-1/LT3485-2/LT3485-3)

The only difference between the four versions of the LT3485 is the peak current level. For the fastest possible charge time, use the LT3485-3. The LT3485-1 has the lowest peak current capability, and is designed for applications that need a more limited drain on the batteries. Due to the lower peak current, the LT3485-1 can use a physically smaller transformer. The LT3485-0 and LT3485-2 have a current limit in between that of the LT3485-3 and the LT3485-1.

#### Transformer Design

The flyback transformer is a key element for any LT3485-0/LT3485-1/LT3485-2/LT3485-3 design. It must be designed carefully and checked that it does not cause excessive current or voltage on any pin of the part. The main parameters that need to be designed are shown in Table 1.

The first transformer parameter that needs to be set is the turns ratio N. The LT3485-0/LT3485-1/LT3485-2/LT3485-3 accomplish output voltage detection by monitoring the flyback waveform on the SW pin. When the SW voltage reaches 31.5V higher than the  $V_{BAT}$  voltage, the part will halt power delivery. Thus, the choice of N sets the target output voltage as it changes the amplitude of the reflected voltage from the output to the SW pin. Choose N according to the following equation:

N =	$V_{OUT} + 2$
	31.5

Table 1.	Recommended	Transformer	Parameters

where  $V_{OUT}$  is the desired output voltage. The number 2 in the numerator is used to include the effect of the voltage drop across the output diode(s).

Thus for a 320V output, N should be 322/31.5 or 10.2. For a 300V output, choose N equal to 302/31.5 or 9.6.

The next parameter that needs to be set is the primary inductance,  $L_{PRI}$ . Choose  $L_{PRI}$  according to the following formula:

$$L_{PRI} \ge \frac{V_{OUT} \bullet 200 \bullet 10^{-9}}{N \bullet I_{PK}}$$

where  $V_{OUT}$  is the desired output voltage. N is the transformer turns ratio.  $I_{PK}$  is 1.4 (LT3485-0), 0.7 (LT3485-1), 1 (LT3485-2) and 2 (LT3485-3).

L<sub>PRI</sub> needs to be equal or larger than this value to ensure that the LT3485-0/LT3485-1/LT3485-2/LT3485-3 has adequate time to respond to the flyback waveform.

All other parameters need to meet or exceed the recommended limits as shown in Table 1. A particularly important parameter is the leakage inductance, L<sub>LEAK</sub>. When the power switch of the LT3485-0/LT3485-1/LT3485-2/ LT3485-3 turns off, the leakage inductance on the primary of the transformer causes a voltage spike to occur on the SW pin. **The height of this spike must not exceed 40V**, even though the absolute maximum rating of the SW Pin is 50V. The 50V absolute maximum rating is a DC blocking voltage specification, which assumes that the current in the power NPN is zero. Figure 3 shows the SW voltage waveform for the circuit of Figure 8 (LT3485-0).

PARAMETER	NAME	TYPICAL RANGE LT3485-0	TYPICAL RANGE LT3485-1	TYPICAL RANGE LT3485-2	TYPICAL RANGE LT3485-3	UNITS
L <sub>PRI</sub>	Primary Inductance	>5	>10	>7	>3.5	μН
L <sub>LEAK</sub>	Primary Leakage Inductance	100 to 300	200 to 500	200 to 500	100 to 300	nH
N	Secondary: Primary Turns Ratio	8 to 12	8 to 12	8 to 12	8 to 12	
V <sub>ISO</sub>	Secondary to Primary Isolation Voltage	>500	>500	>500	>500	V
I <sub>SAT</sub>	Primary Saturation Current	>1.6	>0.8	>1.0	>2	A
R <sub>PRI</sub>	Primary Winding Resistance	<300	<500	<400	<200	mΩ
R <sub>SEC</sub>	Secondary Winding Resistance	<40	<80	<60	<30	Ω

Note that the absolute maximum rating of the SW pin is not exceeded. Make sure to check the SW voltage waveform with  $V_{OUT}$  near the target output voltage, as this is the worst case condition for SW voltage. Figure 4 shows the various limits on the SW voltage during switch turn off.

It is important not to minimize the leakage inductance to a very low level. Although this would result in a very low leakage spike on the SW pin, the parasitic capacitance of the transformer would become large. This will adversely affect the charge time of the photoflash circuit.

Linear Technology has worked with several leading magnetic component manufacturers to produce pre-designed flyback transformers for use with the LT3485-0/LT3485-1/LT3485-2/LT3485-3. Table 2 shows the details of several of these transformers.

Figure 3. LT3485 SW Voltage Waveform

#### **Capacitor Selection**

For the input bypass capacitors, high quality X5R or X7R types should be used. Make sure the voltage capability of the part is adequate.

#### **Output Diode Selection**

The rectifying diode(s) should be low capacitance type with sufficient reverse voltage and forward current ratings. The peak reverse voltage that the diode(s) will see is approximately:

$$V_{\mathsf{PK}-\mathsf{R}} = V_{\mathsf{OUT}} + (\mathsf{N} \bullet \mathsf{V}_{\mathsf{IN}})$$

The peak current of the diode is simply:

$$I_{PK-SEC} = \frac{2}{N} (LT3485-3)$$

$$I_{PK-SEC} = \frac{1.4}{N} (LT3485-0)$$

$$I_{PK-SEC} = \frac{1}{N} (LT3485-2)$$

$$I_{PK-SEC} = \frac{0.7}{N} (LT3485-1)$$

For the circuit of Figure 8 with  $V_{BAT}$  of 5V,  $V_{PK-R}$  is 371V and  $I_{PK-SEC}$  is 137mA. The GSD2004S dual silicon diode is recommended for most LT3485-0/LT3485-1/LT3485-2/LT3485-3 applications. Another option is to use the BAV23S dual silicon diodes. Table 3 shows the various diodes and relevant specifications. Use the appropriate number of diodes to achieve the necessary reverse breakdown voltage.

#### Table 3. Recommended Output Diodes

#### **IGBT Drive**

The IGBT is a high current switch for the 100A+ current through the photoflash lamp. To create a redeve effect or to adjust the light output, the lamp current needs to be stopped, or quenched, with an IGBT before discharging the photoflash capacitor fully. The IGBT device also controls the 4kV trigger pulse required to ionize the xenon gas in the photoflash lamp. Figure 5 is a schematic of a fully functional photoflash application with the LT3485 serving as the IGBT drive. An IGBT drive charges the gate capacitance to start the flash. The IGBT drive does not need to pull-up the gate fast because of the inherently slow nature of the IGBT. A rise time of 2µs is sufficient to charge the gate of the IGBT and create a trigger pulse. With slower rise times, the trigger circuitry will not have a fast enough edge to create the required 4kV pulse. The fall time of the IGBT drive is critical to the safe operation of the IGBT. The IGBT gate is a network of resistors and capacitors, as shown in Figure 6. When the gate terminal is pulled low,

PART	MAX REVERSE VOLTAGE (V)	MAX FORWARD CONTINUOUS CURRENT (mA)	CAPACITANCE (pF)	VENDOR
GSD2004S (Dual Diode)	2x300	225	5	Vishay (402) 563-6866 www.vishay.com

Figure 6. IGBT Gate

the capacitance closest to the terminal goes low but the capacitance further from the terminal remains high. This causes a small portion of the device to handle the full 100A of current, which quickly destroys the device. The pull down circuitry needs to pull down slower than the internal RC time constant in the gate of the IGBT. This is easily accomplished with a resistor in series with the IGBT drive, which is integrated into the LT3485.

The LT3485's integrated drive circuit is independent of the charging function. The IGBT section draws its power from the IGBTPWR pin. The rise and fall times are measured using a 4000pF output capacitor. The typical 10% to 90%

#### Table 4. Recommended IGBTs

rise time is 270ns. The drive pulls high to IGBTPWR. The typical 90% to 10% fall time is 180ns. The drive pulls down to 300mV. The IGBT driver pulls a peak of 150mA when driving an IGBT and 2mA of quiescent current. In the low state, the IGBT's quiescent current is less than  $0.1\mu$ A.

Table 4 is a list of recommended IGBT devices for strobe applications. These three devices are all packaged in 8-lead TSSOP packages.

#### **V<sub>OUT</sub> Monitor**

The voltage output monitor is a new feature to monitor the progress of capacitor charging with a microcontroller. The monitor uses the flyback waveform to output a voltage proportional to the output of the flyback converter. The output monitor voltage range for the pin is 0V to 1V. The 1V output corresponds with the charge cycle terminating and the DONE pin going low. The voltage output monitor is only functional when the circuit is charging (DONE and CHARGE are high.)

#### **Board Layout**

The high voltage operation of the LT3485-0/LT3485-1/ LT3485-2/LT3485-3 demands careful attention to board layout. You will not get advertised performance with careless layout. Figure 7 shows the recommended component placement. Keep the area for the high voltage end of the secondary as small as possible. Also note the larger than minimum spacing for all high voltage nodes in order to meet breakdown voltage requirements for the circuit board. *It is imperative to keep the electrical path formed by C1, the primary of T1, and the LT3485-0/LT3485-1/ LT3485-2/LT3485-3 as short as possible.* If this path is haphazardly made long, it will effectively increase the leakage inductance of T1, which may result in an overvoltage condition on the SW pin.

Figure 7. Suggested Layout: Keep Electrical Path Formed by C1, Transformer Primary and LT3485-0/LT3485-1/LT3485-2/LT3485-3 Short

LTC3440	600mA/1A (I <sub>OUT</sub> ), Synchronous Buck-Boost DC/DC Converter	95% Efficiency, V <sub>IN</sub> : 2.5V to 5.5V, V <sub>OUT(MIN)</sub> = 2.5V to 5.5V, I <sub>Q</sub> = 25µA, I <sub>SD</sub> < 1µA, MS-10 DFN-12
LT3468/LT3468-1/ LT3468-2	Photoflash Capacitors in ThinSOT™	Charges 110µF to 320V in 4.6 Seconds from 3.6V, $V_{IN}$ : 2.5V to 16V, $I_Q$ = 5mA, $I_{SD}$ < 1µA, ThinSOT
LT3472	Dual ±34V, 1.2MHz Boost (350mA)/Inverting (400mA) DC/DC Converter for CCD Bias	Integrated Schottkys, V <sub>IN</sub> : 2.2V to 16V, V <sub>OUT(MAX)</sub> = $\pm$ 34V, I <sub>Q</sub> = 2.5mA, I <sub>SD</sub> < 1µA, DFN
LT3463/LT3463A	Dual Boost (250mA)/Inverting (250mA/400mA) DC/DC Converter for CCD Bias	Integrated Schottkys, VIN: 2.3V to 15V, VOUT(MAX) = $\pm40V,$ I_Q = 40µA, I_{SD} < 1µA, DFN
LT3484-0/LT3484-1/ LT3484-2	Photoflash Capacitor Chargers	Charges 110µF to 320V in 4.6 Seconds from 3.6V, $V_{IN}$ : 2.5V to 16V, $V_{BAT}$ : 1.8V to 16V, $I_Q$ = 5mA, $I_{SD}$ < 1µA, 2mm $\times$ 3mm DFN

ThinSOT is a trademark of Linear Technology Corporation.
