		V_{FB} Ramping Positive	8	10	12	%

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LTC3834E is guaranteed to meet performance specifications from 0°C to 85°C . Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3834I is guaranteed to meet performance specifications over the -40°C to 85°C operating temperature range.

Note 3: T_J is calculated from the ambient temperature T_A and power dissipation P_D according to the following formulas:

$$\text{LTC3834FE: } T_J = T_A + (P_D \cdot 35^\circ\text{C/W})$$

$$\text{LTC3834UFD: } T_J = T_A + (P_D \cdot 37^\circ\text{C/W})$$

Note 4: The LTC3834 is tested in a feedback loop that serves V_{ITH} to a specified voltage and measures the resultant V_{FB} .

Note 5: Dynamic supply current is higher due to the gate charge being delivered at the switching frequency. See Applications Information.

Note 6: Rise and fall times are measured using 10% and 90% levels. Delay times are measured using 50% levels.

Note 7: The minimum on-time condition is specified for an inductor peak-to-peak ripple current $\geq 40\%$ of I_{MAX} (see Minimum On-Time Considerations in the Applications Information section).

PIN FUNCTIONS (FE/UFD)

CLKOUT (Pin 1/Pin 19): Open-Drain Output Clock Signal available to daisy-chain other controller ICs for additional MOSFET driver stages/phases.

PLLLPF (Pin 2/Pin 20): The phase-locked loop's lowpass filter is tied to this pin when synchronizing to an external clock. Alternatively, tie this pin to GND, INTV_{CC} or leave floating to select 250kHz, 530kHz or 400kHz switching frequency.

I_{TH} (Pin 3/Pin 1): Error Amplifier Outputs and Switching Regulator Compensation Points. The current comparator trip point increases with this control voltage.

TRACK/SS (Pin 4/Pin 2): External Tracking and Soft-Start Input. The LTC3834 regulates the V_{FB} voltage to the smaller of 0.8V or the voltage on the TRACK/SS pin. A internal 1μA pull-up current source is connected to this pin. A capacitor to ground at this pin sets the ramp time to final regulated output voltage. Alternatively, a resistor divider on another voltage supply connected to this pin allows the LTC3834 output to track the other supply during start-up.

V_{FB} (Pin 5/Pin 3): Receives the remotely sensed feedback voltage from an external resistive divider across the output.

SGND (Pin 6/Pin 4): Small-Signal Ground. Must be routed separately from high current grounds to the common (–) terminals of the input capacitor.

PGND (Pin 7/Pin 5): Driver Power Ground. Connects to the source of bottom (synchronous) N-channel MOSFET, anode of the Schottky rectifier and the (–) terminal of C_{IN}.

BG (Pin 8/Pin 6): High Current Gate Drive for Bottom (Synchronous) N-Channel MOSFET. Voltage swing at this pin is from ground to INTV_{CC}.

INTV_{CC} (Pin 9/Pin 7): Output of the Internal Linear Low Dropout Regulator. The driver and control circuit are powered from this voltage source. Must be decoupled to power ground with a minimum of 4.7μF tantalum or ceramic capacitor.

EXTV_{CC} (Pin 10/Pin 8): External Power Input to an Internal LDO Connected to INTV_{CC}. This LDO supplies V_{CC} power, bypassing the internal LDO powered from V_{IN} whenever EXTV_{CC} is higher than 4.7V. See EXTV_{CC} Connection in

the Applications Information section. Do not exceed 10V on this pin.

V_{IN} (Pin 11/Pin 9): Main Supply Pin. A bypass capacitor should be tied between this pin and the signal ground pin.

SW (Pin 12/Pin 10): Switch Node Connections to Inductor. Voltage swing at this pin is from a Schottky diode (external) voltage drop below ground to V_{IN}.

TG (Pin 13/Pin 11): High Current Gate Drive for Top N-Channel MOSFET. These are the outputs of floating drivers with a voltage swing equal to INTV_{CC} – 0.5V superimposed on the switch node voltage SW.

BOOST (Pin 14/Pin 12): Bootstrapped Supply to the Topside Floating Driver. A capacitor is connected between the BOOST and SW pins and a Schottky diode is tied between the BOOST and INTV_{CC} pins. Voltage swing at the BOOST pin is from INTV_{CC} to (V_{IN} + INTV_{CC}).

RUN (Pin 15/Pin 13): Digital Run Control Input for Controller. Forcing this pin below 0.7V shuts down all controller functions, reducing the quiescent current that the LTC3834 draws to approximately 4μA.

SENSE[–] (Pin 16/Pin 14): The (–) Input to the Differential Current Comparator.

SENSE⁺ (Pin 17/Pin 15): The (+) Input to the Differential Current Comparator. The I_{TH} pin voltage and controlled offsets between the SENSE[–] and SENSE⁺ pins in conjunction with R_{SENSE} set the current trip threshold.

PGOOD (Pin 18/Pin 16): Open-Drain Logic Output. PGOOD is pulled to ground when the voltage on the V_{FB} pin is not within ±10% of its set point.

PLLIN/MODE (Pin 19/Pin 17): External Synchronization Input to Phase Detector and Forced Continuous Control Input. When an external clock is applied to this pin, the phase-locked loop will force the rising TG signal to be synchronized with the rising edge of the external clock. In this case, an R-C filter must be connected to the PLLPF pin. When not synchronizing to an external clock, this input determines how the LTC3834 operates at light loads. Pulling this pin below 0.7V selects Burst Mode operation. Tying this pin to INTV_{CC} forces continuous inductor current

Exposed Pad (Pin 21/Pin 21): SGND. Must be soldered to the PCB.

PHASMD (Pin 20/Pin 18): Control Input to Phase Selector which determines the phase relationships between TG and the CLKOUT signal.

FUNCTIONAL DIAGRAM

OPERATION (Refer to Functional Diagram)

Main Control Loop

The LTC3834 uses a constant-frequency, current mode step-down architecture. During normal operation, the external top MOSFET is turned on when the clock sets the RS latch, and is turned off when the main current comparator, ICMP, resets the RS latch. The peak inductor current at which ICMP trips and resets the latch is controlled by the voltage on the I_{TH} pin, which is the output of the error amplifier EA. The error amplifier compares the output voltage feedback signal at the V_{FB} pin, (which is generated with an external resistor divider connected across the output voltage, V_{OUT} , to ground) to the internal 0.800V reference voltage. When the load current increases, it causes a slight decrease in V_{FB} relative to the reference, which cause the EA to increase the I_{TH} voltage until the average inductor current matches the new load current.

After the top MOSFET is turned off each cycle, the bottom MOSFET is turned on until either the inductor current starts to reverse, as indicated by the current comparator IR, or the beginning of the next clock cycle.

INTV_{CC}/EXTV_{CC} Power

Power for the top and bottom MOSFET drivers and most other internal circuitry is derived from the INTV_{CC} pin. When the EXTV_{CC} pin is left open or tied to a voltage less than 4.7V, an internal 5.25V low dropout linear regulator supplies INTV_{CC} power from V_{IN} . If EXTV_{CC} is taken above 4.7V, the 5.25V regulator is turned off and a 7.5V low dropout linear regulator is enabled that supplies INTV_{CC} power from EXTV_{CC}. If EXTV_{CC} is less than 7.5V (but greater than 4.7V), the 7.5V regulator is in dropout and INTV_{CC} is approximately equal to EXTV_{CC}. When EXTV_{CC} is greater than 7.5V (up to an absolute maximum rating of 10V), INTV_{CC} is regulated to 7.5V. Using the EXTV_{CC} pin allows the INTV_{CC} power to be derived from a high efficiency external source such as one of the LTC3834 switching regulator outputs.

The top MOSFET driver is biased from the floating bootstrap capacitor, C_B , which normally recharges during each off cycle through an external diode when the top MOSFET turns off. If the input voltage V_{IN} decreases to a voltage close to V_{OUT} , the loop may enter dropout and attempt to turn on the top MOSFET continuously. The dropout detector detects this and forces the top MOSFET off for about one twelfth of the clock period every tenth cycle to allow C_B to recharge.

Shutdown and Start-Up (RUN and TRACK/SS Pins)

The LTC3834 can be shut down using the RUN pin. Pulling this pin below 0.7V shuts down the main control loop of the controller. A low disables the controller and most internal circuits, including the INTV_{CC} regulator, at which time the LTC3834 draws only 4 μ A of quiescent current.

Releasing the RUN pin allows an internal 0.5 μ A current to pull up the pin and enable that controller. Alternatively, the RUN pin may be externally pulled up or driven directly by logic. Be careful not to exceed the Absolute Maximum rating of 7V on this pin.

The start-up of the output voltage V_{OUT} is controlled by the voltage on the TRACK/SS pin. When the voltage on the TRACK/SS pin is less than the 0.8V internal reference, the LTC3834 regulates the V_{FB} voltage to the TRACK/SS pin voltage instead of the 0.8V reference. This allows the TRACK/SS pin to be used to program a soft-start by connecting an external capacitor from the TRACK/SS pin to SGND. An internal 1 μ A pull-up current charges this capacitor creating a voltage ramp on the TRACK/SS pin. As the TRACK/SS voltage rises linearly from 0V to 0.8V (and beyond), the output voltage V_{OUT} rises smoothly from zero to its final value.

Alternatively the TRACK/SS pin can be used to cause the start-up of V_{OUT} to "track" that of another supply. Typically, this requires connecting to the TRACK/SS pin an external resistor divider from the other supply to ground (see Applications Information section).

OPERATION (Refer to Functional Diagram)

When the RUN pin is pulled low to disable the LTC3834, or when V_{IN} drops below its undervoltage lockout threshold of 3.7V, the TRACK/SS pin is pulled low by an internal MOSFET. When in undervoltage lockout, the controller is disabled and the external MOSFETs are held off.

Light Load Current Operation (Burst Mode Operation, Pulse-Skipping or Continuous Conduction) (PLLIN/MODE Pin)

The LTC3834 can be enabled to enter high efficiency Burst Mode operation, constant-frequency pulse-skipping mode, or forced continuous conduction mode at low load currents. To select Burst Mode operation, tie the PLLIN/MODE pin to a DC voltage below 0.8V (e.g., SGND). To select forced continuous operation, tie the PLLIN/MODE pin to $INTV_{CC}$. To select pulse skipping mode, tie the PLLIN/MODE pin to a DC voltage greater than 0.8V and less than $INTV_{CC} - 0.5V$.

When the LTC3834 is enabled for Burst Mode operation, the peak current in the inductor is set to approximately one-tenth of the maximum sense voltage even though the voltage on the I_{TH} pin indicates a lower value. If the average inductor current is lower than the load current, the error amplifier EA will decrease the voltage on the I_{TH} pin. When the I_{TH} voltage drops below 0.4V, the internal sleep signal goes high (enabling “sleep” mode) and both external MOSFETs are turned off. The I_{TH} pin is then disconnected from the output of the EA and “parked” at 0.425V.

In sleep mode, much of the internal circuitry is turned off, reducing the quiescent current that the LTC3834 draws to only 30 μ A. In sleep mode, the load current is supplied by the output capacitor. As the output voltage decreases, the EA’s output begins to rise. When the output voltage drops enough, the I_{TH} pin is reconnected to the output of the EA, the sleep signal goes low, and the controller

resumes normal operation by turning on the top external MOSFET on the next cycle of the internal oscillator.

When the LTC3834 is enabled for Burst Mode operation, the inductor current is not allowed to reverse. The reverse current comparator (RI_{CMP}) turns off the bottom external MOSFET just before the inductor current reaches zero, preventing it from reversing and going negative, thus operating in discontinuous operation.

In forced continuous operation, the inductor current is allowed to reverse at light loads or under large transient conditions. The peak inductor current is determined by the voltage on the I_{TH} pin, just as in normal operation. In this mode, the efficiency at light loads is lower than in Burst Mode operation. However, continuous operation has the advantages of lower output ripple and less interference to audio circuitry. In forced continuous mode, the output ripple is independent of load current.

When the PLLIN/MODE pin is connected for pulse skipping mode or clocked by an external clock source to use the phase-locked loop (see Frequency Selection and Phase-Locked Loop section), the LTC3834 operates in PWM pulse skipping mode at light loads. In this mode, constant-frequency operation is maintained down to approximately 1% of designed maximum output current. At very light loads, the current comparator ICMP may remain tripped for several cycles and force the external top MOSFET to stay off for the same number of cycles (i.e., skipping pulses). The inductor current is not allowed to reverse (discontinuous operation). This mode, like forced continuous operation, exhibits low output ripple as well as low audio noise and reduced RF interference as compared to Burst Mode operation. It provides higher low current efficiency than forced continuous mode, but not nearly as high as Burst Mode operation.

OPERATION

Frequency Selection and Phase-Locked Loop (PLLLPF and PLLIN/MODE Pins)

The selection of switching frequency is a trade-off between efficiency and component size. Low frequency operation increases efficiency by reducing MOSFET switching losses, but requires larger inductance and/or capacitance to maintain low output ripple voltage.

The switching frequency of the LTC3834's controllers can be selected using the PLLLPF pin.

If the PLLIN/MODE pin is not being driven by an external clock source, the PLLLPF pin can be floated, tied to INTVCC, or tied to SGND to select 400kHz, 530kHz or 250kHz, respectively.

A phase-locked loop (PLL) is available on the LTC3834 to synchronize the internal oscillator to an external clock source that is connected to the PLLIN/MODE pin. In this case, a series R-C should be connected between the PLLLPF pin and SGND to serve as the PLL's loop filter. The LTC3834 phase detector adjusts the voltage on the PLLLPF pin to align the turn-on of the external top MOSFET to the rising edge of the synchronizing signal.

The typical capture range of the LTC3834's phase-locked loop is from approximately 115kHz to 800kHz, with a guarantee to be between 140kHz and 650kHz. In other words, the LTC3834's PLL is guaranteed to lock to an external clock source whose frequency is between 140kHz and 650kHz.

The typical input clock thresholds on the PLLIN/MODE pin are 1.6V (rising) and 1.2V (falling).

PolyPhase Applications (CLKOUT and PHASMD Pins)

The LTC3834 features two pins (CLKOUT and PHASMD) that allow other controller ICs to be daisy-chained with the LTC3834 in PolyPhase applications. The clock output

signal on the CLKOUT pin can be used to synchronize additional power stages in a multiphase power supply solution feeding a single, high current output or multiple separate outputs. The PHASMD pin is used to adjust the phase of the CLKOUT signal, as summarized in Table 1. The phases are calculated relative to the zero degrees phase being defined as the rising edge of the top gate driver output (TG).

The CLKOUT pin has an open-drain output device. Normally, a 10k to 100k resistor can be connected from this pin to a voltage supply that is less than or equal to 8.5V.

Table 1

V _{PHASMD}	CLKOUT PHASE
GND	90°
Floating	120°
INTV _{CC}	180°

Output Overvoltage Protection

An overvoltage comparator guards against transient overshoots as well as other more serious conditions that may overvoltage the output. When the V_{FB} pin rises to more than 10% higher than its regulation point of 0.800V, the top MOSFET is turned off and the bottom MOSFET is turned on until the overvoltage condition is cleared.

Power Good (PGOOD) Pin

The PGOOD pin is connected to an open-drain of an internal N-channel MOSFET. The MOSFET turns on and pulls the PGOOD pin low when the V_{FB} pin voltage is not within ±10% of the 0.8V reference voltage. The PGOOD pin is also pulled low when the RUN pin is low (shut down). When the V_{FB} pin voltage is within the ±10% requirement, the MOSFET is turned off and the pin is allowed to be pulled up by an external resistor to a source of up to 8.5V.

APPLICATIONS INFORMATION

R_{SENSE} Selection For Output Current

R_{SENSE} is chosen based on the required output current. The current comparator has a maximum threshold of 100mV/R_{SENSE} and an input common mode range of SGND to 10V. The current comparator threshold sets the peak of the inductor current, yielding a maximum average output current I_{MAX} equal to the peak value less half the peak-to-peak ripple current, ΔI_L .

Allowing a margin for variations in the IC and external component values yields:

$$R_{\text{SENSE}} = \frac{80\text{mV}}{I_{\text{MAX}}}$$

When using the controller in very low dropout conditions, the maximum output current level will be reduced due to the internal compensation required to meet stability criterion for buck regulators operating at greater than 50% duty factor. A curve is provided to estimate this reduction in peak output current level depending upon the operating duty factor.

Operating Frequency and Synchronization

The choice of operating frequency, is a trade-off between efficiency and component size. Low frequency operation improves efficiency by reducing MOSFET switching losses, both gate charge loss and transition loss. However, lower frequency operation requires more inductance for a given amount of ripple current.

The internal oscillator of the LTC3834 runs at a nominal 400kHz frequency when the PLLLPF pin is left floating and the PLLIN/MODE pin is a DC low or high. Pulling the PLLLPF to INTVCC selects 530kHz operation; pulling the PLLLPF to SGND selects 250kHz operation.

Alternatively, the LTC3834 will phase-lock to a clock signal applied to the PLLIN/MODE pin with a frequency between 140kHz and 650kHz (see Phase-Locked Loop and Frequency Synchronization).

Inductor Value Calculation

The operating frequency and inductor selection are inter-related in that higher operating frequencies allow the use of smaller inductor and capacitor values. So why would

anyone ever choose to operate at lower frequencies with larger components? The answer is efficiency. A higher frequency generally results in lower efficiency because of MOSFET gate charge losses. In addition to this basic trade-off, the effect of inductor value on ripple current and low current operation must also be considered.

The inductor value has a direct effect on ripple current. The inductor ripple current ΔI_L decreases with higher inductance or frequency and increases with higher V_{IN}:

$$\Delta I_L = \frac{1}{(f)(L)} V_{\text{OUT}} \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right)$$

Accepting larger values of ΔI_L allows the use of low inductances, but results in higher output voltage ripple and greater core losses. A reasonable starting point for setting ripple current is $\Delta I_L = 0.3(I_{\text{MAX}})$. The maximum ΔI_L occurs at the maximum input voltage.

The inductor value also has secondary effects. The transition to Burst Mode operation begins when the average inductor current required results in a peak current below 10% of the current limit determined by R_{SENSE}. Lower inductor values (higher ΔI_L) will cause this to occur at lower load currents, which can cause a dip in efficiency in the upper range of low current operation. In Burst Mode operation, lower inductance values will cause the burst frequency to decrease.

Inductor Core Selection

Once the value for L is known, the type of inductor must be selected. High efficiency converters generally cannot afford the core loss found in low cost powdered iron cores, forcing the use of more expensive ferrite or molypermalloy cores. Actual core loss is independent of core size for a fixed inductor value, but it is very dependent on inductance selected. As inductance increases, core losses go down. Unfortunately, increased inductance requires more turns of wire and therefore copper losses will increase.

Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can concentrate on copper loss and preventing saturation. Ferrite core material saturates "hard," which means that inductance collapses abruptly when the peak design current is

APPLICATIONS INFORMATION

exceeded. This results in an abrupt increase in inductor ripple current and consequent output voltage ripple. Do not allow the core to saturate!

Power MOSFET and Schottky Diode (Optional) Selection

Two external power MOSFETs must be selected for the LTC3834: one N-channel MOSFET for the top (main) switch, and one N-channel MOSFET for the bottom (synchronous) switch.

The peak-to-peak drive levels are set by the $INTV_{CC}$ voltage. This voltage is typically 5V during start-up (see $EXTV_{CC}$ Pin Connection). Consequently, logic-level threshold MOSFETs must be used in most applications. The only exception is if low input voltage is expected ($V_{IN} < 5V$); then, sub-logic level threshold MOSFETs ($V_{GS(TH)} < 3V$) should be used. Pay close attention to the BV_{DSS} specification for the MOSFETs as well; most of the logic-level MOSFETs are limited to 30V or less.

Selection criteria for the power MOSFETs include the “ON” resistance $R_{DS(ON)}$, Miller capacitance C_{MILLER} , input voltage and maximum output current. Miller capacitance, C_{MILLER} , can be approximated from the gate charge curve usually provided on the MOSFET manufacturers’ data sheet. C_{MILLER} is equal to the increase in gate charge along the horizontal axis while the curve is approximately flat divided by the specified change in V_{DS} . This result is then multiplied by the ratio of the application applied V_{DS} to the Gate charge curve specified V_{DS} . When the IC is operating in continuous mode the duty cycles for the top and bottom MOSFETs are given by:

$$\text{Main Switch Duty Cycle} = \frac{V_{OUT}}{V_{IN}}$$

$$\text{Synchronous Switch Duty Cycle} = \frac{V_{IN} - V_{OUT}}{V_{IN}}$$

The MOSFET power dissipations at maximum output current are given by:

$$P_{MAIN} = \frac{V_{OUT}}{V_{IN}} (I_{MAX})^2 (1 + \delta \Delta T) R_{DS(ON)} + (V_{IN})^2 \left(\frac{I_{MAX}}{2} \right) (R_{DR}) (C_{MILLER}) \cdot \left[\frac{1}{V_{INTVCC} - V_{THMIN}} + \frac{1}{V_{THMIN}} \right] (f)$$

$$P_{SYNC} = \frac{V_{IN} - V_{OUT}}{V_{IN}} (I_{MAX})^2 (1 + \delta \Delta T) R_{DS(ON)}$$

where δ is the temperature dependency of $R_{DS(ON)}$ and R_{DR} (approximately 2Ω) is the effective driver resistance at the MOSFET’s Miller threshold voltage. V_{THMIN} is the typical MOSFET minimum threshold voltage.

Both MOSFETs have I^2R losses while the topside N-channel equation includes an additional term for transition losses, which are highest at high input voltages. For $V_{IN} < 20V$ the high current efficiency generally improves with larger MOSFETs, while for $V_{IN} > 20V$ the transition losses rapidly increase to the point that the use of a higher $R_{DS(ON)}$ device with lower C_{MILLER} actually provides higher efficiency. The synchronous MOSFET losses are greatest at high input voltage when the top switch duty factor is low or during a short-circuit when the synchronous switch is on close to 100% of the period.

The term $(1 + \delta \Delta T)$ is generally given for a MOSFET in the form of a normalized $R_{DS(ON)}$ vs Temperature curve, but $\delta = 0.005/^{\circ}C$ can be used as an approximation for low voltage MOSFETs.

The optional Schottky diode D1 shown in Figure 6 conducts during the dead-time between the conduction of the two power MOSFETs. This prevents the body diode of the bottom MOSFET from turning on, storing charge during the dead-time and requiring a reverse recovery period that could cost as much as 3% in efficiency at high V_{IN} . A 1A to 3A Schottky is generally a good compromise for both regions of operation due to the relatively small average current. Larger diodes result in additional transition losses due to their larger junction capacitance.

APPLICATIONS INFORMATION

C_{IN} and C_{OUT} Selection

In continuous mode, the source current of the top MOSFET is a square wave of duty cycle (V_{OUT})/(V_{IN}). To prevent large voltage transients, a low ESR capacitor sized for the maximum RMS current must be used. The maximum RMS capacitor current is given by:

$$C_{IN} \text{ Required } I_{RMS} \approx \frac{I_{MAX}}{V_{IN}} \left[(V_{OUT})(V_{IN} - V_{OUT}) \right]^{1/2}$$

This formula has a maximum at $V_{IN} = 2V_{OUT}$, where $I_{RMS} = I_{OUT}/2$. This simple worst-case condition is commonly used for design because even significant deviations do not offer much relief. Note that capacitor manufacturers' ripple current ratings are often based on only 2000 hours of life. This makes it advisable to further derate the capacitor, or to choose a capacitor rated at a higher temperature than required. Several capacitors may be paralleled to meet size or height requirements in the design. Due to the high operating frequency of the LTC3834, ceramic capacitors can also be used for C_{IN} . Always consult the manufacturer if there is any question.

The selection of C_{OUT} is driven by the effective series resistance (ESR). Typically, once the ESR requirement is satisfied, the capacitance is adequate for filtering. The output ripple (ΔV_{OUT}) is approximated by:

$$\Delta V_{OUT} \approx I_{RIPPLE} \left(ESR + \frac{1}{8fC_{OUT}} \right)$$

where f is the operating frequency, C_{OUT} is the output capacitance and I_{RIPPLE} is the ripple current in the inductor. The output ripple is highest at maximum input voltage since I_{RIPPLE} increases with input voltage.

Setting Output Voltage

The LTC3834 output voltage is set by an external feedback resistor divider carefully placed across the output, as shown in Figure 1. The regulated output voltage is determined by:

$$V_{OUT} = 0.8V \cdot \left(1 + \frac{R_B}{R_A} \right)$$

Figure 1. Setting Output Voltage

Figure 2. SENSE Pins Input Bias Current vs Common Mode Voltage

To improve the frequency response, a feed-forward capacitor, C_{FF} , may be used. Great care should be taken to route the V_{FB} line away from noise sources, such as the inductor and the SW line.

SENSE⁺ and SENSE⁻ Pins

The common mode input range of the current comparator is from 0V to 10V. Continuous linear operation is provided throughout this range allowing output voltages from 0.8V to 10V. The input stage of the current comparator requires that current either be sourced or sunk from the SENSE pins depending on the output voltage, as shown in the curve in Figure 2. If the output voltage is below 1.5V, current will flow out of both SENSE pins to the main output. In these cases, the output can be easily pre-loaded by the V_{OUT} resistor divider to compensate for the current comparator's negative input bias current. Since V_{FB} is servoed to the 0.8V reference voltage, R_A in Figure 1 should be chosen to be less than $0.8V/I_{SENSE}$, with I_{SENSE} determined from Figure 2 at the specified output voltage.

APPLICATIONS INFORMATION

Tracking and Soft-Start (TRACK/SS Pin)

The start-up of V_{OUT} is controlled by the voltage on the TRACK/SS pin. When the voltage on the TRACK/SS pin is less than the internal 0.8V reference, the LTC3834 regulates the V_{FB} pin voltage to the voltage on the TRACK/SS pin instead of 0.8V. The TRACK/SS pin can be used to program an external soft-start function or to allow V_{OUT} to “track” another supply during start-up.

Soft-start is enabled by simply connecting a capacitor from the TRACK/SS pin to ground, as shown in Figure 3. An internal 1 μ A current source charges up the capacitor, providing a linear ramping voltage at the TRACK/SS pin. The LTC3834 will regulate the V_{FB} pin (and hence V_{OUT})

Figure 3. Using the TRACK/SS Pin to Program Soft-Start

(4a) Coincident Tracking

(4b) Ratiometric Tracking

Figure 4. Two Different Modes of Output Voltage Tracking

Figure 5. Using the TRACK/SS Pin for Tracking

according to the voltage on the TRACK/SS pin, allowing V_{OUT} to rise smoothly from 0V to its final regulated value. The total soft-start time will be approximately:

$$t_{ss} = C_{ss} \cdot \frac{0.8V}{1\mu A}$$

Alternatively, the TRACK/SS pin can be used to track two (or more) supplies during start-up, as shown qualitatively in Figures 4a and 4b. To do this, a resistor divider should be connected from the master supply (V_X) to the TRACK/SS pin of the slave supply (V_{OUT}), as shown in Figure 5. During start-up V_{OUT} will track V_X according to the ratio set by the resistor divider:

$$\frac{V_X}{V_{OUT}} = \frac{R_A}{R_{TRACKA}} \cdot \frac{R_{TRACKA} + R_{TRACKB}}{R_A + R_B}$$

For coincident tracking ($V_{OUT} = V_X$ during start-up),

$$R_A = R_{TRACKA}$$

$$R_B = R_{TRACKB}$$

APPLICATIONS INFORMATION

INTV_{CC} Regulators

The LTC3834 features two separate internal P-channel low dropout linear regulators (LDO) that supply power at the INTV_{CC} pin from either the V_{IN} supply pin or the EXTV_{CC} pin, respectively, depending on the connection of the EXTV_{CC} pin. INTV_{CC} powers the gate drivers and much of the LTC3834's internal circuitry. The V_{IN} LDO regulates the voltage at the INTV_{CC} pin to 5.25V and the EXTV_{CC} LDO regulates it to 7.5V. Each of these can supply a peak current of 50mA and must be bypassed to ground with a minimum of 4.7μF ceramic capacitor. The ceramic capacitor placed directly adjacent to the INTV_{CC} and PGND IC pins is highly recommended. Good bypassing is needed to supply the high transient currents required by the MOSFET gate drivers and to prevent interaction between the channels.

High input voltage applications in which large MOSFETs are being driven at high frequencies may cause the maximum junction temperature rating for the LTC3834 to be exceeded. The INTV_{CC} current, which is dominated by the gate charge current, may be supplied by either the 5V V_{IN} LDO or the 7.5V EXTV_{CC} LDO. When the voltage on the EXTV_{CC} pin is less than 4.7V, the V_{IN} LDO is enabled. Power dissipation for the IC in this case is highest and is equal to $V_{IN} \cdot I_{INTVCC}$. The gate charge current is dependent on operating frequency as discussed in the Efficiency Considerations section. The junction temperature can be estimated by using the equations given in Note 3 of the Electrical Characteristics. For example, the LTC3834 INTV_{CC} current is limited to less than 41mA from a 24V supply when in the G package and not using the EXTV_{CC} supply:

$$T_J = 70^{\circ}\text{C} + (41\text{mA})(36\text{V})(95^{\circ}\text{C/W}) = 125^{\circ}\text{C}$$

To prevent the maximum junction temperature from being exceeded, the input supply current must be checked while operating in continuous conduction mode (PLLIN/MODE = INTV_{CC}) at maximum V_{IN}.

When the voltage applied to EXTV_{CC} rises above 4.7V, the V_{IN} LDO is turned off and the EXTV_{CC} LDO is enabled. The EXTV_{CC} LDO remains on as long as the voltage applied to EXTV_{CC} remains above 4.5V. The EXTV_{CC} LDO attempts to regulate the INTV_{CC} voltage to 7.5V, so while EXTV_{CC} is less than 7.5V, the LDO is in dropout and the INTV_{CC} voltage is approximately equal to EXTV_{CC}. When EXTV_{CC}

is greater than 7.5V up to an absolute maximum of 10V, INTV_{CC} is regulated to 7.5V.

Using the EXTV_{CC} LDO allows the MOSFET driver and control power to be derived from the LTC3834 switching regulator output ($4.7\text{V} \leq V_{OUT} \leq 10\text{V}$) during normal operation and from the V_{IN} LDO when the output is out of regulation (e.g., start-up, short circuit). If more current is required through the EXTV_{CC} LDO than is specified, an external Schottky diode can be added between the EXTV_{CC} and INTV_{CC} pins. Do not apply more than 10V to the EXTV_{CC} pin and make sure that $\text{EXTV}_{CC} \leq V_{IN}$.

Significant efficiency and thermal gains can be realized by powering INTV_{CC} from the output, since the V_{IN} current resulting from the driver and control currents will be scaled by a factor of (Duty Cycle)/(Switcher Efficiency). For 4.7V to 10V regulator outputs, this means connecting the EXTV_{CC} pin directly to V_{OUT}. Tying the EXTV_{CC} pin to a 5V supply reduces the junction temperature in the previous example from 125°C to:

$$T_J = 70^{\circ}\text{C} + (24\text{mA})(5\text{V})(95^{\circ}\text{C/W}) = 81^{\circ}\text{C}$$

However, for 3.3V and other low voltage outputs, additional circuitry is required to derive INTV_{CC} power from the output.

The following list summarizes the four possible connections for EXTV_{CC}:

1. EXTV_{CC} Left Open (or Grounded). This will cause INTV_{CC} to be powered from the internal 5.25V regulator resulting in an efficiency penalty of up to 10% at high input voltages.
2. EXTV_{CC} Connected Directly to V_{OUT}. This is the normal connection for a 5V regulator and provides the highest efficiency.
3. EXTV_{CC} Connected to an External supply. If an external supply is available in the 5V to 7V range, it may be used to power EXTV_{CC} providing it is compatible with the MOSFET gate drive requirements.
4. EXTV_{CC} Connected to an Output-Derived Boost Network. For 3.3V and other low voltage regulators, efficiency gains can still be realized by connecting EXTV_{CC} to an output-derived voltage that has been boosted to greater than 4.7V. This can be done with the capacitive charge pump shown in Figure 6.

APPLICATIONS INFORMATION

Topside MOSFET Driver Supply (C_B , D_B)

External bootstrap capacitors, C_B , connected to the BOOST pins supply the gate drive voltages for the topside MOSFET. Capacitor C_B in the Functional Diagram is charged through external diode D_B from $INTV_{CC}$ when the SW pin is low. When the topside MOSFET is to be turned on, the driver places the C_B voltage across the gate-source of the desired MOSFET. This enhances the MOSFET and turns on the topside switch. The switch node voltage, SW, rises to V_{IN} and the BOOST pin follows. With the topside MOSFET on, the boost voltage is above the input supply: $V_{BOOST} = V_{IN} + V_{INTV_{CC}}$. The value of the boost capacitor, C_B , needs to be 100 times that of the total input capacitance of the topside MOSFET. The reverse breakdown of the external Schottky diode must be greater than $V_{IN(MAX)}$. When adjusting the gate drive level, the final arbiter is the total input current for the regulator. If a change is made and the input current decreases, then the efficiency has improved. If there is no change in input current, then there is no change in efficiency.

Figure 6. Capacitive Charge Pump for EXTV_{CC}

Fault Conditions: Current Limit and Current Foldback

The LTC3834 includes current foldback to help limit load current when the output is shorted to ground. If the output falls below 70% of its nominal output level, then the maximum sense voltage is progressively lowered from 100mV to 30mV. Under short-circuit conditions with very low duty cycles, the LTC3834 will begin cycle skipping in order to limit the short-circuit current. In this situation the bottom MOSFET will be dissipating most of the power but less than in normal operation. The short-circuit ripple current is determined by the minimum on-time, $t_{ON(MIN)}$, of the LTC3834 ($\approx 200\text{ns}$), the input voltage and inductor value:

$$\Delta I_{L(SC)} = t_{ON(MIN)} (V_{IN}/L)$$

The resulting short-circuit current is:

$$I_{SC} = \frac{30\text{mV}}{R_{SENSE}} - \frac{1}{2} \Delta I_{L(SC)}$$

Fault Conditions: Overvoltage Protection (Crowbar)

The overvoltage crowbar is designed to blow a system input fuse when the output voltage of the regulator rises much higher than nominal levels. The crowbar causes huge currents to flow, that blow the fuse to protect against a shorted top MOSFET if the short occurs while the controller is operating.

A comparator monitors the output for overvoltage conditions. The comparator (OV) detects overvoltage faults greater than 10% above the nominal output voltage. When this condition is sensed, the top MOSFET is turned off and the bottom MOSFET is turned on until the overvoltage condition is cleared. The bottom MOSFET remains on continuously for as long as the overvoltage condition persists; if V_{OUT} returns to a safe level, normal operation automatically resumes. A shorted top MOSFET will result in a high current condition which will open the system fuse. The switching regulator will regulate properly with a leaky top MOSFET by altering the duty cycle to accommodate the leakage.

APPLICATIONS INFORMATION

Phase-Locked Loop and Frequency Synchronization

The LTC3834 has a phase-locked loop (PLL) comprised of an internal voltage-controlled oscillator (VCO) and a phase detector. This allows the turn-on of the top MOSFET (TG) to be locked to the rising edge of an external clock signal applied to the PLLIN/MODE pin. The phase detector is an edge sensitive digital type that provides zero degrees phase shift between the external and internal oscillators. This type of phase detector does not exhibit false lock to harmonics of the external clock.

The output of the phase detector is a pair of complementary current sources that charge or discharge the external filter network connected to the PLLLPF pin. The relationship between the voltage on the PLLLPF pin and operating frequency, when there is a clock signal applied to PLLIN/MODE, is shown in Figure 7 and specified in the Electrical Characteristics table. Note that the LTC3834 can only be synchronized to an external clock whose frequency is within range of the LTC3834's internal VCO, which is nominally 115kHz to 800kHz. This is guaranteed to be between 140kHz and 650kHz. A simplified block diagram is shown in Figure 8.

3835 F07

Figure 7. Relationship Between Oscillator Frequency and Voltage at the PLLLPF Pin When Synchronizing to an External Clock

If the external clock frequency is greater than the internal oscillator's frequency, f_{OSC} , then current is sourced continuously from the phase detector output, pulling up the PLLLPF pin. When the external clock frequency is less than f_{OSC} , current is sunk continuously, pulling down the PLLLPF pin. If the external and internal frequencies are the same but exhibit a phase difference, the current sources turn on for an amount of time corresponding to the phase difference. The voltage on the PLLLPF pin is adjusted until the phase and frequency of the internal and external oscillators are identical. At the stable operating point, the phase detector output is high impedance and the filter capacitor C_{LP} holds the voltage.

The loop filter components, C_{LP} and R_{LP} , smooth out the current pulses from the phase detector and provide a stable input to the voltage-controlled oscillator. The filter components C_{LP} and R_{LP} determine how fast the loop acquires lock. Typically $R_{LP} = 10k$ and C_{LP} is 2200pF to 0.01 μ F.

Typically, the external clock (on PLLIN/MODE pin) input high threshold is 1.6V, while the input low threshold is 1.2V.

Figure 8. Phase-Locked Loop Block Diagram

APPLICATIONS INFORMATION

Table 2 summarizes the different states in which the PLLLPF pin can be used.

Table 2

PLLLPF PIN	PLLIN/MODE PIN	FREQUENCY
0V	DC Voltage	250kHz
Floating	DC Voltage	400kHz
INTV _{CC}	DC Voltage	530kHz
RC Loop Filter	Clock Signal	Phase-Locked to External Clock

Minimum On-Time Considerations

Minimum on-time, $t_{ON(MIN)}$, is the smallest time duration that the LTC3834 is capable of turning on the top MOSFET. It is determined by internal timing delays and the gate charge required to turn on the top MOSFET. Low duty cycle applications may approach this minimum on-time limit and care should be taken to ensure that

$$t_{ON(MIN)} < \frac{V_{OUT}}{V_{IN}(f)}$$

If the duty cycle falls below what can be accommodated by the minimum on-time, the controller will begin to skip cycles. The output voltage will continue to be regulated, but the ripple voltage and current will increase.

The minimum on-time for the LTC3834 is approximately 200ns. However, as the peak sense voltage decreases the minimum on-time gradually increases up to about 250ns. This is of particular concern in forced continuous applications with low ripple current at light loads. If the duty cycle drops below the minimum on-time limit in this situation, a significant amount of cycle skipping can occur with correspondingly larger current and voltage ripple.

Efficiency Considerations

The percent efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Percent efficiency can be expressed as:

$$\% \text{Efficiency} = 100\% - (L1 + L2 + L3 + \dots)$$

where L1, L2, etc. are the individual losses as a percentage of input power.

Although all dissipative elements in the circuit produce losses, four main sources usually account for most of the losses in LTC3834 circuits: 1) IC V_{IN} current, 2) INT- V_{CC} regulator current, 3) I^2R losses, 4) Topside MOSFET transition losses.

1. The V_{IN} current has two components: the first is the DC supply current given in the Electrical Characteristics table, which excludes MOSFET driver and control currents; the second is the current drawn from the 3.3V linear regulator output. V_{IN} current typically results in a small ($< 0.1\%$) loss.
2. INTV_{CC} current is the sum of the MOSFET driver and control currents. The MOSFET driver current results from switching the gate capacitance of the power MOSFETs. Each time a MOSFET gate is switched from low to high to low again, a packet of charge dQ moves from INTV_{CC} to ground. The resulting dQ/dt is a current out of INTV_{CC} that is typically much larger than the control circuit current. In continuous mode, $I_{GATECHG} = f(Q_T + Q_B)$, where Q_T and Q_B are the gate charges of the topside and bottom side MOSFETs.

Supplying INTV_{CC} power through the EXT_{VCC} switch input from an output-derived source will scale the V_{IN} current required for the driver and control circuits by a factor of (Duty Cycle)/(Efficiency). For example, in a 20V to 5V application, 10mA of INTV_{CC} current results in approximately 2.5mA of V_{IN} current. This reduces the mid-current loss from 10% or more (if the driver was powered directly from V_{IN}) to only a few percent.

3. I^2R losses are predicted from the DC resistances of the fuse (if used), MOSFET, inductor, current sense resistor, and input and output capacitor ESR. In continuous mode the average output current flows through L and R_{SENSE} , but is "chopped" between the topside MOSFET and the synchronous MOSFET. If the two MOSFETs have approximately the same $R_{DS(ON)}$, then the resistance of one MOSFET can simply be summed with the resistances of L, R_{SENSE} and ESR to obtain I^2R losses. For example, if each $R_{DS(ON)} = 30m\Omega$, $R_L = 50m\Omega$, $R_{SENSE} = 10m\Omega$ and $R_{ESR} = 40m\Omega$ (sum of both input and output capacitance losses), then the total resistance is 130m Ω . This results in losses ranging from 3% to 13% as the output current increases from 1A to 5A for

3834fc

APPLICATIONS INFORMATION

a 5V output, or a 4% to 20% loss for a 3.3V output. Efficiency varies as the inverse square of V_{OUT} for the same external components and output power level. The combined effects of increasingly lower output voltages and higher currents required by high performance digital systems is not doubling but quadrupling the importance of loss terms in the switching regulator system!

4. Transition losses apply only to the topside MOSFET, and become significant only when operating at high input voltages (typically 15V or greater). Transition losses can be estimated from:

$$\text{Transition Loss} = (1.7) V_{IN}^2 I_{O(MAX)} C_{RSS} f$$

Other “hidden” losses such as copper trace and internal battery resistances can account for an additional 5% to 10% efficiency degradation in portable systems. It is very important to include these “system” level losses during the design phase. The internal battery and fuse resistance losses can be minimized by making sure that C_{IN} has adequate charge storage and very low ESR at the switching frequency. A 25W supply will typically require a minimum of 20 μ F to 40 μ F of capacitance having a maximum of 20m Ω to 50m Ω of ESR. Other losses including Schottky conduction losses during dead-time and inductor core losses generally account for less than 2% total additional loss.

Checking Transient Response

The regulator loop response can be checked by looking at the load current transient response. Switching regulators take several cycles to respond to a step in DC (resistive) load current. When a load step occurs, V_{OUT} shifts by an amount equal to ΔI_{LOAD} (ESR), where ESR is the effective series resistance of C_{OUT} . ΔI_{LOAD} also begins to charge or discharge C_{OUT} generating the feedback error signal that forces the regulator to adapt to the current change and return V_{OUT} to its steady-state value. During this recovery time V_{OUT} can be monitored for excessive overshoot or ringing, which would indicate a stability problem. OPTI-LOOP compensation allows the transient response to be optimized over a wide range of output capacitance and ESR values. *The availability of the I_{TH} pin not only allows optimization of control loop behavior but also provides a DC coupled and AC filtered closed-loop response*

test point. The DC step, rise time and settling at this test point truly reflects the closed-loop response. Assuming a predominantly second order system, phase margin and/or damping factor can be estimated using the percentage of overshoot seen at this pin. The bandwidth can also be estimated by examining the rise time at the pin. The I_{TH} external components shown in the Typical Application circuit will provide an adequate starting point for most applications.

The I_{TH} series R_C - C_C filter sets the dominant pole-zero loop compensation. The values can be modified slightly (from 0.5 to 2 times their suggested values) to optimize transient response once the final PC layout is done and the particular output capacitor type and value have been determined. The output capacitors need to be selected because the various types and values determine the loop gain and phase. An output current pulse of 20% to 80% of full-load current having a rise time of 1 μ s to 10 μ s will produce output voltage and I_{TH} pin waveforms that will give a sense of the overall loop stability without breaking the feedback loop. Placing a power MOSFET directly across the output capacitor and driving the gate with an appropriate signal generator is a practical way to produce a realistic load step condition. The initial output voltage step resulting from the step change in output current may not be within the bandwidth of the feedback loop, so this signal cannot be used to determine phase margin. This is why it is better to look at the I_{TH} pin signal which is in the feedback loop and is the filtered and compensated control loop response. The gain of the loop will be increased by increasing R_C and the bandwidth of the loop will be increased by decreasing C_C . If R_C is increased by the same factor that C_C is decreased, the zero frequency will be kept the same, thereby keeping the phase shift the same in the most critical frequency range of the feedback loop. The output voltage settling behavior is related to the stability of the closed-loop system and will demonstrate the actual overall supply performance.

A second, more severe transient is caused by switching in loads with large (>1 μ F) supply bypass capacitors. The discharged bypass capacitors are effectively put in parallel with C_{OUT} , causing a rapid drop in V_{OUT} . No regulator can alter its delivery of current quickly enough to prevent this

APPLICATIONS INFORMATION

sudden step change in output voltage if the load switch resistance is low and it is driven quickly. If the ratio of C_{LOAD} to C_{OUT} is greater than 1:50, the switch rise time should be controlled so that the load rise time is limited to approximately $25 \cdot C_{LOAD}$. Thus a 10 μ F capacitor would require a 250 μ s rise time, limiting the charging current to about 200mA.

Design Example

As a design example, assume $V_{IN} = 12V$ (nominal), $V_{IN} = 22V$ (max), $V_{OUT} = 1.8V$, $I_{MAX} = 5A$, and $f = 250kHz$.

The inductance value is chosen first based on a 30% ripple current assumption. The highest value of ripple current occurs at the maximum input voltage. Tie the PLLPF pin to GND, generating 250kHz operation. The minimum inductance for 30% ripple current is:

$$\Delta I_L = \frac{V_{OUT}}{(f)(L)} \left(1 - \frac{V_{OUT}}{V_{IN}} \right)$$

A 4.7 μ H inductor will produce 23% ripple current and a 3.3 μ H will result in 33%. The peak inductor current will be the maximum DC value plus one half the ripple current, or 5.84A, for the 3.3 μ H value. Increasing the ripple current will also help ensure that the minimum on-time of 180ns is not violated. The minimum on-time occurs at maximum V_{IN} :

$$t_{ON(MIN)} = \frac{V_{OUT}}{V_{IN(MAX)} f} = \frac{1.8V}{22V(250kHz)} = 327ns$$

The R_{SENSE} resistor value can be calculated by using the maximum current sense voltage specification with some accommodation for tolerances:

$$R_{SENSE} \leq \frac{80mV}{5.84A} \approx 0.012\Omega$$

Choosing 1% resistors: $R1 = 25.5k$ and $R2 = 32.4k$ yields an output voltage of 1.816V.

The power dissipation on the topside MOSFET can be easily estimated. Choosing a Fairchild FDS6982S dual MOSFET results in: $R_{DS(ON)} = 0.035\Omega/0.022\Omega$, $C_{MILLER} = 215pF$. At maximum input voltage with T (estimated) = 50°C:

$$P_{MAIN} = \frac{1.8V}{22V} (5)^2 [1 + (0.005)(50^\circ C - 25^\circ C)] \cdot$$

$$(0.035\Omega) + (22V)^2 \left(\frac{5A}{2} \right) (4\Omega) (215pF) \cdot$$

$$\left[\frac{1}{5-2.3} + \frac{1}{2.3} \right] (300kHz) = 332mW$$

A short-circuit to ground will result in a folded back current of:

$$I_{SC} = \frac{25mV}{0.01\Omega} - \frac{1}{2} \left(\frac{120ns(22V)}{3.3\mu H} \right) = 2.1A$$

with a typical value of $R_{DS(ON)}$ and $\delta = (0.005/^\circ C)(20) = 0.1$. The resulting power dissipated in the bottom MOSFET is:

$$P_{SYNC} = \frac{22V - 1.8V}{22V} (2.1A)^2 (1.125)(0.022\Omega) = 100mW$$

which is less than under full-load conditions.

C_{IN} is chosen for an RMS current rating of at least 3A at temperature assuming only this channel is on. C_{OUT} is chosen with an ESR of 0.02 Ω for low output ripple. The output ripple in continuous mode will be highest at the maximum input voltage. The output voltage ripple due to ESR is approximately:

$$V_{ORIPPLE} = R_{ESR} (\Delta I_L) = 0.02\Omega (1.67A) = 33mV_{P-P}$$

PC Board Layout Checklist

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the IC. These items are also illustrated graphically in the layout diagram of Figure 9. The Figure 10 illustrates the current waveforms present in the various branches of the synchronous regulator operating in the continuous mode. Check the following in your layout:

1. Is the top N-channel MOSFET M1 located within 1cm of C_{IN} ?
2. Are the signal and power grounds kept separate? The combined IC signal ground pin and the ground return of $C_{INTV_{CC}}$ must return to the combined C_{OUT} (–) terminals. The path formed by the top N-channel MOSFET, Schottky diode and the C_{IN} capacitor should have short leads and PC trace lengths. The output capacitor (–) terminals should be connected as close as possible to the (–) terminals of the input capacitor by placing the capacitors next to each other and away from the Schottky loop described above.
3. Does the LTC3834 V_{FB} pin resistive divider connect to the (+) terminals of C_{OUT} ? The resistive divider must be connected between the (+) terminal of C_{OUT} and signal ground. The feedback resistor connections should not be along the high current input feeds from the input capacitor(s).
4. Are the $SENSE^-$ and $SENSE^+$ leads routed together with minimum PC trace spacing? The filter capacitor between $SENSE^+$ and $SENSE^-$ should be as close as possible to the IC. Ensure accurate current sensing with Kelvin connections at the SENSE resistor.
5. Is the $INTV_{CC}$ decoupling capacitor connected close to the IC, between the $INTV_{CC}$ and the power ground pins? This capacitor carries the MOSFET drivers current peaks. An additional 1 μ F ceramic capacitor placed immediately next to the $INTV_{CC}$ and PGND pins can help improve noise performance substantially.
6. Keep the switching node (SW), top gate node (TG), and boost node (BOOST) away from sensitive small-signal nodes. All of these nodes have very large and fast moving signals and therefore should be kept on the

“output side” of the LTC3834 and occupy minimum PC trace area.

7. Use a modified “star ground” technique: a low impedance, large copper area central grounding point on the same side of the PC board as the input and output capacitors with tie-ins for the bottom of the $INTV_{CC}$ decoupling capacitor, the bottom of the voltage feedback resistive divider and the SGND pin of the IC.

PC Board Layout Debugging

It is helpful to use a DC-50MHz current probe to monitor the current in the inductor while testing the circuit. Monitor the output switching node (SW pin) to synchronize the oscilloscope to the internal oscillator and probe the actual output voltage as well. Check for proper performance over the operating voltage and current range expected in the application. The frequency of operation should be maintained over the input voltage range down to dropout and until the output load drops below the low current operation threshold—typically 10% of the maximum designed current level in Burst Mode operation.

The duty cycle percentage should be maintained from cycle to cycle in a well-designed, low noise PCB implementation. Variation in the duty cycle at a subharmonic rate can suggest noise pickup at the current or voltage sensing inputs or inadequate loop compensation. Overcompensation of the loop can be used to tame a poor PC layout if regulator bandwidth optimization is not required.

Reduce V_{IN} from its nominal level to verify operation of the regulator in dropout. Check the operation of the undervoltage lockout circuit by further lowering V_{IN} while monitoring the outputs to verify operation.

Investigate whether any problems exist only at higher output currents or only at higher input voltages. If problems coincide with high input voltages and low output currents, look for capacitive coupling between the BOOST, SW, TG, and possibly BG connections and the sensitive voltage and current pins. The capacitor placed across the current sensing pins needs to be placed immediately adjacent to the pins of the IC. This capacitor helps to minimize the effects of differential noise injection due to high frequency capacitive coupling. If problems are encountered with

APPLICATIONS INFORMATION

high current output loading at lower input voltages, look for inductive coupling between C_{IN} , Schottky and the top MOSFET components to the sensitive current and voltage sensing traces. In addition, investigate common ground path voltage pickup between these components and the SGND pin of the IC.

An embarrassing problem, which can be missed in an otherwise properly working switching regulator, results

when the current sensing leads are hooked up backwards. The output voltage under this improper hookup will still be maintained but the advantages of current mode control will not be realized. Compensation of the voltage loop will be much more sensitive to component selection. This behavior can be investigated by temporarily shorting out the current sensing resistor—don't worry, the regulator will still maintain control of the output voltage.

TYPICAL APPLICATIONS

High Efficiency 9.5V, 3A Step-Down Converter

High Efficiency 12V to 1.8V, 2A Step-Down Converter

TYPICAL APPLICATIONS

High Efficiency 5V, 5A Step-Down Converter

TYPICAL APPLICATIONS

High Efficiency 1.2V, 5A Step-Down Converter

PACKAGE DESCRIPTION

FE Package 20-Lead Plastic TSSOP (4.4mm) (Reference LTC DWG # 05-08-1663) Exposed Pad Variation CB

UFD Package 20-Lead Plastic QFN (4mm × 5mm) (Reference LTC DWG # 05-08-1711 Rev B)

REVISION HISTORY

REV	DATE	DESCRIPTION	PAGE NUMBER
C	02/15	Changed V_{IN} to $INTV_{CC}$ in PLLPF pin function description.	8

TYPICAL APPLICATION

RELATED PARTS

PART NUMBER	DESCRIPTION	COMMENTS
LTC1735	High Efficiency Synchronous Step-Down Switching Regulator	Output Fault Protection, 16-Pin SSOP
LTC1778/ LTC1778-1	No R _{SENSE} ™ Current Mode Synchronous Step-Down Controllers	Up to 97% Efficiency, $4V \leq V_{IN} \leq 36V$, $0.8V \leq V_{OUT} \leq (0.9)(V_{IN})$, I _{OUT} Up to 20A
LTC3708	Dual, 2-Phase, DC/DC Controller with Output Tracking	Current Mode, No R _{SENSE} , Up/Down Tracking, Synchronizable
LTC3727/ LTC3727-1	High Efficiency, 2-Phase, Synchronous Step-Down Switching Regulators	2-Phase Operation; $4V \leq V_{IN} \leq 36V$, $0.8V \leq V_{OUT} \leq 14V$, 99% Duty Cycle, 5mm × 5mm QFN, SSOP-28
LTC3728	Dual, 550kHz, 2-Phase Synchronous Step-Down Controller	Dual 180° Phased Controllers, V _{IN} 3.5V to 35V, 99% Duty Cycle, 5mm × 5mm QFN, SSOP-28
LTC3729	20A to 200A, 550kHz PolyPhase Synchronous Controller	Expandable from 2-Phase to 12-Phase, Uses All Surface Mount Components, V _{IN} Up to 36V
LTC3731	3- to 12-Phase Step-Down Synchronous Controller	60A to 240A Output Current, $0.6V \leq V_{OUT} \leq 6V$, $4.5V \leq V_{IN} \leq 32V$
LT3800	High Voltage Synchronous Regulator Controller	V _{IN} up to 60V, I _{OUT} ≤ 20A, Current Mode, Onboard Bias Regulator, Burst Mode Operation, 16-Lead TSSOP Package
LTC3826/ LTC3826-1	30μA I _Q , Dual, 2-Phase Synchronous Step-Down Controller	2-Phase Operation; 30μA One Channel No-Load I _Q (50μA Total), $4V \leq V_{IN} \leq 36V$, $0.8V \leq V_{OUT} \leq 10V$
LTC3827/ LTC3827-1	Low I _Q Dual Synchronous Controller	2-Phase Operation; 115μA Total No Load I _Q , $4V \leq V_{IN} \leq 36V$ 80μA No-Load I _Q with One Channel On
LTC3835/ LTC3835-1	Low I _Q Synchronous Step-Down Controller	80μA No Load I _Q , $4V \leq V_{IN} \leq 36V$, $0.8V \leq V_{OUT} \leq 10V$
LT3844	High Voltage Current Mode Controller with Programmable Operating Frequency	V _{IN} up to 60V, I _{OUT} ≤ 5A Onboard Bias Regulator, Burst Mode Operation, Sync Capability, 16-Lead TSSOP Package
LT3845	Low I _Q Synchronous Step-Down Controller	$4V \leq V_{IN} \leq 60V$, $1.23V \leq V_{OUT} \leq 36V$, 120μA Quiescent Current
LTC3850	Dual, 2-Phase Synchronous Step-Down DC/DC Controller	2-Phase Operation; $4V \leq V_{IN} \leq 24V$, 95% Efficiency, No R _{SENSE} Option, I _{OUT} up to 20A, 4mm × 4mm QFN
