Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LTC5582IDD is guaranteed functional over the case temperature range -40°C to 105°C . All limits at -40°C and 105°C are guaranteed by design and production sample testing.

Note 3: The LTC5582HDD is guaranteed functional over the case temperature range -40°C to 125°C . All limits at -40°C and 125°C are guaranteed by 100% production testing.

Note 4: Logarithmic Intercept is an extrapolated input power level from the best fitted log-linear straight line, where the output voltage is 0V.

Note 5: Operation over a wider frequency range is possible with reduced performance. Consult the factory for information and assistance.

Note 6: The linearity error is calculated by the difference between the incremental slope of the output and the average output slope from -50dBm to -5dBm for frequencies up to 5.8GHz, and -25dBm to -5dBm for 8GHz and 10GHz. The dynamic range is defined as the range over which the linearity error is within $\pm 1\text{dB}$.

PIN FUNCTIONS

V_{CC} (Pin 1): Power Supply Pin. Typical current consumption is 41.6mA at room temperature. This pin should be externally bypassed with 1nF and 1μF chip capacitors.

IN⁺, IN⁻ (Pins 2, 4): Differential Input Signal Pins. Either one can be driven with a single-ended signal while the other is AC-coupled to ground. These pins can also be driven with a differential signal. The pins are internally biased to 1.585V and should be DC blocked externally. The differential impedance is typically 400Ω. The impedance of each pin to the DEC pin is 200Ω.

DEC (Pin 3): Input Common Mode Decoupling Pin. This pin is internally biased to 1.585V and connected to an on-chip 50pF capacitor to ground. The impedance between DEC and IN⁺ (or IN⁻) is 200Ω. The pin can be connected to the center tap of an external balun when terminated differentially. The pin can be floating or connected to ground via an AC-decoupling capacitor when driven either in single-ended or differential input configuration.

GND (Pin 5, Exposed Pad Pin 11): Circuit Ground Return for the Entire IC. This must be soldered to the printed circuit board ground plane.

OUT (Pin 6): DC Output Pin. The output impedance is mainly determined by an internal 100Ω series resistance which provides protection if the output is shorted to ground.

RT2 (Pin 7): Optional Control Pin for 2nd-Order Output Temperature Compensation. Connect this pin to ground to disable it. The output voltage will decrease with respect to the room temperature (25°C) by connecting it to ground via an off-chip resistor when the ambient temperature is either higher or lower.

RT1 (Pin 8): Optional Control Pin for 1st-Order Output Temperature Compensation. Connect this pin to ground to disable it. The output voltage will increase inversely proportional to ambient temperature.

EN (Pin 9): Enable Pin. An applied voltage above 1V will activate the bias for the IC. For an applied voltage below 0.4V, the circuits will be shut down (disabled) with a reduction in power supply current. If the enable function is not required, then this pin can be connected to V_{CC}. Typical enable pin input current is 100μA for EN = 3.3V. Note that at no time should the Enable pin voltage be allowed to exceed V_{CC} by more than 0.3V.

FLTR (Pin 10): Connection for an External Filtering Capacitor C3. A minimum of 8nF capacitance is required for stable AC average power measurement. This capacitor should be connected to V_{CC}.

APPLICATIONS INFORMATION

The LTC5582 is a true RMS RF power detector, capable of measuring an RF signal over the frequency range from 40MHz to 10GHz, independent of input waveforms with different crest factors such as CW, CDMA2K, WCDMA, LTE and WiMAX signals. Up to 60dB dynamic range is achieved with a very stable output within the full temperature range from -40°C to 125°C . Its sensitivity can be as low as -57dBm up to 2.7GHz even with single-ended 50 Ω input termination.

RF Inputs

The differential RF inputs are internally biased at 1.585V. The differential impedance is 400 Ω . These pins should be DC blocked when connected to ground or other matching components.

The LTC5582 can be driven in a single-ended configuration as illustrated in Figure 3. The single-ended input impedance vs frequency is detailed in Table 1. The DEC Pin can be either left floating or AC-coupled to ground via an external capacitor. While the RF signal is applied to the IN⁺ (or IN⁻) Pin, the other pin IN⁻ (or IN⁺) should be AC-coupled to ground. By simply terminating a 68 Ω resistor between the IN⁺ and IN⁻ Pins and coupling the non-signal side to ground using a 1nF capacitor, broadband 50 Ω input matching can be achieved with typical return loss better than 10dB from 40MHz to 5.5GHz. At higher RF frequencies, additional matching components may be needed.

6000	23.3-j7.5	0.377	-158.4

The LTC5582 differential inputs can also be driven from a fully balanced source as shown in Figure 4. When the signal source is a single-ended 50 Ω , conversion to a differential signal can be achieved using a 1:8 balun to match the internal 400 Ω input impedance to the 50 Ω source. This impedance transformation results in 9dB voltage gain, thus 9dB improvement in sensitivity is obtained

APPLICATIONS INFORMATION

while the overall dynamic range remains the same. At high frequency, additional LC elements may be needed for the input impedance matching due to the parasitics of the transformer and PCB traces.

Figure 4. Differential Input Configuration

Due to the high input impedance of the LTC5582, a narrow band L-C matching network can be also used to convert a single-ended input to differential signal as shown in Figure 5. By this means, the sensitivity and overall linear dynamic range of the detector will be very similar to the one using 1:8 RF input balun. The conversion gain is strongly dependent on the loss (or Q) of the matching network, particularly at high frequency. The lower the Q, the lower the conversion gain. However, the matching bandwidth is correspondingly wider. The following formulas are provided to calculate the input matching network for single-ended-to-differential conversion at low RF frequency (i.e., below 1GHz).

$$C_{S1} = C_{S2} = \frac{1}{\pi f_c \sqrt{50 R_{IN}}} = \frac{2.25 \cdot 10^9}{f_c} \quad (\text{pF})$$

$$L_M = \frac{\sqrt{50 R_{IN}}}{2\pi f_c} = \frac{2.25 \cdot 10^{10}}{f_c} \quad (\text{nH})$$

where R_{IN} is the differential input resistance (400Ω) and f_c is the center RF operating frequency.

As an example, Figure 6 shows that good input return loss is achieved from 300MHz to 400MHz when $C_{S1} = C_{S2} = 6.8\text{pF}$ and $L_M = 66\text{nH}$. Figure 7 show the sensitivity is also improved by 8dB at 350MHz while the dynamic

Figure 5. Single-Ended-to-Differential Conversion

Figure 6. RF Input Return Loss

Figure 7. Output Voltage vs RF Input Power

range remains the same.

Although these equations give a good starting point, it is usually necessary to adjust the component values after building and testing the circuit. As the RF operating frequency increases, the real values of C_{S1} , C_{S2} , L_M will deviate from the above equations due to parasitics of the components, device and PCB layout.

APPLICATIONS INFORMATION

For a 50Ω input termination, the approximate RF input power range of the LTC5582 is from -60dBm to 2dBm , even with high crest factor signals such as a 4-carrier W-CDMA waveform, and the minimum detectable RF power level varies as the input RF frequency increases. The linear dynamic range can also be shifted to suit a particular application need. By simply inserting an attenuator in front of the RF input, the power range is shifted higher by the amount of the attenuation.

The sensitivity of LTC5582 is dictated by the broadband input noise power that also determines the output DC offset voltage. When the inputs are terminated differently, the DC output voltage may vary slightly. When the input noise power is minimized, the DC offset voltage is also reduced to the minimum. And the detector's sensitivity and dynamic range will be improved accordingly.

External Filtering (FLTR) Capacitor

This pin is internally biased at $V_{CC} - 0.43\text{V}$ via a $1.2\text{k}\Omega$ resistor from the voltage supply, V_{CC} . To assure stable operation of the LTC5582, an external capacitor C3 with a value of 8nF or higher is required to connect from the FLTR Pin to V_{CC} to avoid an abnormal start-up condition. Don't connect this filtering capacitor to ground or any other low voltage reference at any time.

This external capacitor value has a dominant effect on the output transient response. The lower the capacitance, the faster the output rise and fall times. For signals with AM content such as W-CDMA, significant ripple can be observed when the loop bandwidth set by C3 is close to the modulation bandwidth of the signal. A 4-carrier W-CDMA RF signal is used as an example in this case. The trade-offs of the residual ripple vs the output transient times are as shown in Figure 8.

In general, the LTC5582 output ripple remains relatively constant regardless of the RF input power level for a fixed C3 and modulation format of the RF signal. Typically, C3 must be selected to smooth out the ripple to achieve the desired accuracy of RF power measurement.

Output Interface

The output buffer amplifier of the LTC5582 is shown in Figure 9. This Class AB buffer amplifier can source and

Figure 8. Residual Ripple, Output Transient Times vs Filtering Capacitor C3

Figure 9. Simplified Schematic of the Output Interface

sink 5mA current to and from the load. The output impedance is determined primarily by the 100Ω series resistor connected to the output of the buffer amplifier inside the chip. This will prevent overstress on internal devices in the event that the output is shorted to ground.

The -3dB small-signal bandwidth of the buffer amplifier is about 22.4MHz and the full-scale rise/fall time can be as fast as 80ns , limited by the slew rate of the internal circuit instead. When the output is resistively terminated or open, the fastest output transient response is achieved when a large signal is applied to the RF input. The rise time of the LTC5582 is about 90ns and the fall time is $5\mu\text{s}$, respectively, for full-scale pulsed RF input power when $C3 = 8\text{nF}$. The speed of the output transient response is dictated mainly by the filtering capacitor C3 (at least 8nF) at the FLTR Pin. See the detailed output transient response in the Typical Performance Characteristics section. When the RF input has AM content, residual ripple may be present at the output depending upon the low frequency content of the modulated RF signal. This ripple can be reduced with a

APPLICATIONS INFORMATION

larger filtering capacitor C3 at the expense of a slower transient response.

Since the output buffer amplifier of the LTC5582 is capable of driving an arbitrary capacitive load, the residual ripple can be further filtered at the output with a series resistor R_{SS} and a large shunt capacitor C_{LOAD} . See Figure 9. This lowpass filter also reduces the output noise by limiting the output noise bandwidth. When this RC network is designed properly, a fast output transient response can be maintained with a reduced residual ripple. For example, we can estimate C_{LOAD} with an output voltage swing of 1.7V at 2140MHz. In order not to allow the maximum 5mA sourcing current to limit the fall time (about 5 μ s), the maximum value of C_{LOAD} can be chosen as follows:

$$C_{LOAD} \leq 5\text{mA} \cdot \frac{\text{allowable additional time}}{1.7\text{V}} =$$

$$5\text{mA} \cdot \frac{0.25\mu\text{s}}{1.7\text{V}} = 735\text{pF}$$

Once C_{LOAD} is determined, R_{SS} can be chosen properly to form a RC low-pass filter with a corner frequency of $1/[2\pi(R_{SS} + 100) \cdot C_{LOAD}]$.

In general, the rise time of the LTC5582 is much shorter than the fall time. However, when the output RC filter is used, the rise time can be dominated by the time constant of this filter. Accordingly, the rise time becomes very similar to the fall time. Although the maximum sinking capability of the LTC5582 is 5mA, it is recommended that the output load resistance should be greater than 1.2k in order to achieve the full output voltage swing.

Temperature Compensation of Logarithmic Intercept

The simplified interface schematic of the intercept temperature compensation is shown in Figure 10. The adjustment of the output voltage can be described by the following equation with respect to the ambient temperature:

$$\Delta V_{OUT} = -TC1 \cdot (T_A - T_{NOM}) - TC2 \cdot (T_A - T_{NOM})^2 - \text{detV1} - \text{detV2}$$

where TC1 and TC2 are the 1st-order and 2nd-order temperature compensation coefficients, respectively; T_A is the actual ambient temperature; and T_{NOM} is the reference room temperature; detV1 and detV2 are the output

voltage variations when R_{T1} and R_{T2} are not set to zero at room temperature. The temperature coefficients TC1 and

Figure 10. Simplified Interface Circuit Schematic of the Control Pins R_{T1} and R_{T2}

TC2 are shown as functions of the tuning resistors R_{T1} and R_{T2} in Figures 11 and 12, respectively.

When Pins $RT1$ and $RT2$ are shorted to ground, the temperature compensation circuit is disabled automatically. Table 2 lists the suggested R_{T1} and R_{T2} values at various

Enable Interface

A simplified schematic of the EN Pin interface is shown in Figure 13. The enable voltage necessary to turn on the LTC5582 is 1V. To disable or turn off the chip, this voltage should be below 0.4V. It is important that the voltage applied to the EN pin should never exceed V_{CC} by more than 0.3V. Otherwise, the supply current may be sourced through the upper ESD protection diode connected at the EN pin. Under no circumstances should voltage be applied to the EN Pin before the supply voltage is applied to the V_{CC} pin. If this occurs, damage to the IC may result.

Supply Voltage Ramping

Fast ramping of the supply voltage can cause a current glitch in the internal ESD protection circuits. Depending on the supply inductance, this could result in a supply voltage overshooting at the initial transient that exceeds the maximum rating. A supply voltage ramp time of greater than 1ms is recommended. In case this voltage ramp time is not controllable, a small (i.e., 1.5Ω) series resistor should be inserted in-between V_{CC} Pin and the supply voltage source to mitigate the problem and self-protect the IC. The R1 shown in Figure 1 is served for this purpose.

DD Package
10-Lead Plastic DFN (3mm × 3mm)
 (Reference LTC DWG # 05-08-1699 Rev C)

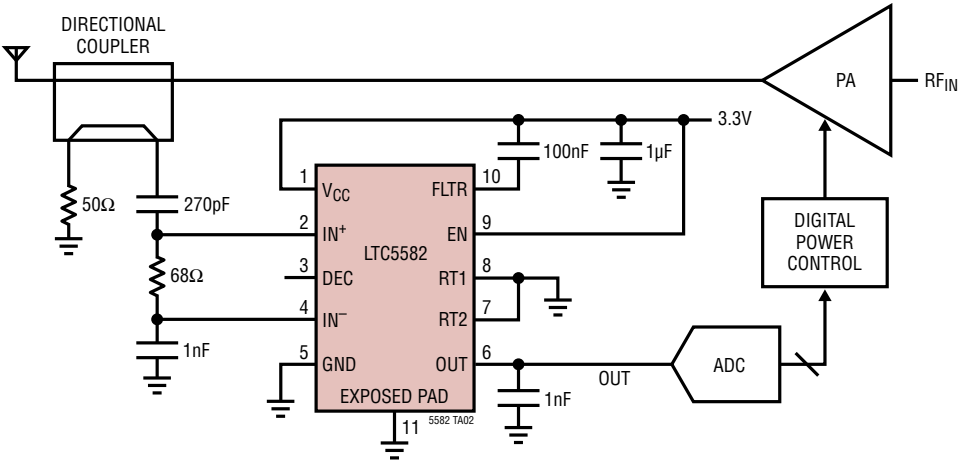

1. DRAWING TO BE MADE A JEDEC PACKAGE OUTLINE M0-229 VARIATION OF (WEED-2).
CHECK THE LTC WEBSITE DATA SHEET FOR CURRENT STATUS OF VARIATION ASSIGNMENT
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE
MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE
TOP AND BOTTOM OF PACKAGE

REVISION HISTORY

REV	DATE	DESCRIPTION	PAGE NUMBER
A	06/18	Changed LTC5582IDD#PBF and LTC5582IDD#TRPBF temperature range to –40°C to 105°C. Added a LTC5582HDD#PBF and LTC5582HDD#TRPBF grade with temperature range of –40°C to 125°C. Extended Typical Performance Characteristics plots to include 125°C case, where applicable.	2
B	11/19	Add automotive-qualified versions of this product.	1, 2

TYPICAL APPLICATION

40MHz to 6GHz Infrastructure Power Amplifier Level Control

RELATED PARTS
