**Absolute Maximum Ratings<sup>(1)</sup>**

Supply Voltage ( $V_{IN}$ )..... 0V to +6V  
 Enable Input Voltage ( $V_{EN}$ )..... 0V to +6V  
 Power Dissipation..... Internally Limited<sup>(3)</sup>  
 Lead Temperature (soldering, 3sec)..... 260°C  
 Storage Temperature ( $T_S$ )..... -65°C to +150°C  
 ESD Rating<sup>(4)</sup> ..... 2kV

**Operating Ratings<sup>(2)</sup>**

Supply voltage ( $V_{IN}$ )..... +2.3V to +5.5V  
 Enable Input Voltage ( $V_{EN}$ )..... 0V to  $V_{IN}$   
 Junction Temperature ..... -40°C to +125°C  
 Junction Thermal Resistance  
 Thin MLF<sup>®</sup>-6 ( $\theta_{JA}$ ) ..... 100°C/W

**Electrical Characteristics<sup>(5)</sup>**

$V_{IN} = EN1 = EN2 = V_{OUT} + 1.0V$ ; higher of the two regulator outputs,  $I_{OUTLDO1} = I_{OUTLDO2} = 100\mu A$ ;  $C_{OUT1} = C_{OUT2} = 1\mu F$ ;  
 $T_J = 25^\circ C$ , **bold** values indicate  $-40^\circ C \leq T_J \leq +125^\circ C$ , unless noted.

**Notes:**

- Exceeding the absolute maximum rating may damage the device.
- The device is not guaranteed to function outside its operating rating.
- The maximum allowable power dissipation of any  $T_A$  (ambient temperature) is  $P_{D(max)} = (T_{J(max)} - T_A) / \theta_{JA}$ . Exceeding the maximum allowable power dissipation will result in excessive die temperature, and the regulator will go into thermal shutdown.
- Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5k in series with 100pF.
- Specification for packaged product only.
- Dropout voltage is defined as the input-to-output differential at which the output voltage drops 2% below its nominal  $V_{OUT}$ . For outputs below 2.3V, the dropout voltage is the input-to-output differential with the minimum input voltage 2.3V.

## Typical Characteristics

## Functional Characteristics

## Applications Information

### Enable/Shutdown

The MIC5335 comes with dual active-high enable pins that allow each regulator to be enabled independently. Forcing the enable pin low disables the regulator and sends it into a “zero” off-mode-current state. In this state, current consumed by the regulator goes nearly to zero. Forcing the enable pin high enables the output voltage. The active-high enable pin uses CMOS technology and the enable pin cannot be left floating; a floating enable pin may cause an indeterminate state on the output.

### Input Capacitor

The MIC5335 is a high-performance, high bandwidth device. Therefore, it requires a well-bypassed input supply for optimal performance. A 1μF capacitor is required from the input-to-ground to provide stability. Low-ESR ceramic capacitors provide optimal performance at a minimum of space. Additional high-frequency capacitors, such as small-valued NPO dielectric-type capacitors, help filter out high-frequency noise and are good practice in any RF-based circuit.

### Output Capacitor

The MIC5335 requires an output capacitor of 1μF or greater to maintain stability. The design is optimized for use with low-ESR ceramic chip capacitors. High ESR capacitors may cause high frequency oscillation. The output capacitor can be increased, but performance has been optimized for a 1μF ceramic output capacitor and does not improve significantly with larger capacitance.

X7R/X5R dielectric-type ceramic capacitors are recommended because of their temperature performance. X7R-type capacitors change capacitance by 15% over their operating temperature range and are the most stable type of ceramic capacitors on the market. Z5U and Y5V dielectric capacitors change value by as much as 50% and 60%, respectively, over their operating temperature ranges. To use a ceramic chip capacitor with Y5V dielectric, the value must be much higher than an X7R ceramic capacitor to ensure the same minimum capacitance over the equivalent operating temperature range.

### No-Load Stability

Unlike many other voltage regulators, the MIC5335 will remain stable and in regulation with no load. This is especially important in CMOS RAM keep-alive applications.

## Thermal Considerations

The MIC5335 is designed to provide 300mA of continuous current for both outputs in a very small package. Maximum ambient operating temperature can be calculated based upon the output current and the voltage drop across the part. Given that the input voltage is 3.3V, the output voltage is 2.8V for V<sub>OUT1</sub>, 2.5V for V<sub>OUT2</sub> and the output current = 300mA. The actual power dissipation of the regulator circuit can be determined using the equation:

$$P_D = (V_{IN} - V_{OUT1}) I_{OUT1} + (V_{IN} - V_{OUT2}) I_{OUT2} + V_{IN} I_{GND}$$

Because this device is CMOS and the ground current is typically <100μA over the load range, the power dissipation contributed by the ground current is < 1% and can be ignored for this calculation.

$$P_D = (3.3V - 2.8V) \times 300mA + (3.3V - 2.5V) \times 300mA$$

$$P_D = 0.39W$$

To determine the maximum ambient operating temperature of the package, use the junction-to-ambient thermal resistance of the device and the following basic equation:

$$P_{D(max)} = \left( \frac{T_{J(max)} - T_A}{\theta_{JA}} \right)$$

T<sub>J(max)</sub> = 125°C, the maximum junction temperature of the die θ<sub>JA</sub> thermal resistance = 100°C/W.

The table that follows shows junction-to-ambient thermal resistance for the MIC5335 in the Thin MLF® package.

| Package                     | θ <sub>JA</sub><br>Recommended<br>Minimum<br>Footprint | θ <sub>JC</sub> |
|-----------------------------|--------------------------------------------------------|-----------------|
| 6-Pin 1.6 X1.6<br>Thin MLF™ | 100°C/W                                                | 2°C/W           |

### Thermal Resistance

Substituting P<sub>D</sub> for P<sub>D(max)</sub> and solving for the ambient operating temperature will give the maximum operating conditions for the regulator circuit. The junction-to-ambient thermal resistance for the minimum footprint is 100°C/W.

The maximum power dissipation must not be exceeded for proper operation.

For example, when operating the MIC5335-MFYML at an input voltage of 3.3V and 300mA loads on each output with a minimum footprint layout, the maximum ambient operating temperature T<sub>A</sub> can be determined as follows:

$$0.39W = (125^\circ C - T_A)/(100^\circ C/W)$$

$$T_A = 86^{\circ}\text{C}$$

Therefore, a 2.8V/2.5V application with 300mA at each output current can accept an ambient operating temperature of 86°C in a 1.6mm x 1.6mm Thin MLF<sup>®</sup> package. For a full discussion of heat sinking and
