Application Information

Microprocessor Reset

The /RESET pin is asserted whenever V_{CC} falls below the reset threshold voltage, V_{TH}. The /RESET pin remains asserted for the duration of the reset timeout period (t_{RESET}) after V_{CC} has risen above the reset threshold voltage. The reset function ensures the microprocessor is properly reset and powers up in a known condition after a power failure. /RESET will remain valid with V_{CC} as low as 1.0V.

The /RESET output is a simple open-drain N-channel MOSFET structure. A pull-up resistor must be used to pull this output up to some voltage. For most applications, this voltage will be the same power supply that supplies V_{CC} to the MIC803. As shown in Figure 1, it is possible, however, to tie this resistor to some other voltage. This will allow the MIC803 to monitor one voltage while level-shifting the /RESET output to some other voltage. The pull-up voltage must be limited to 5.5V. The resistor must be small enough to supply current to the inputs and leakage paths that are driven by the /RESET output.

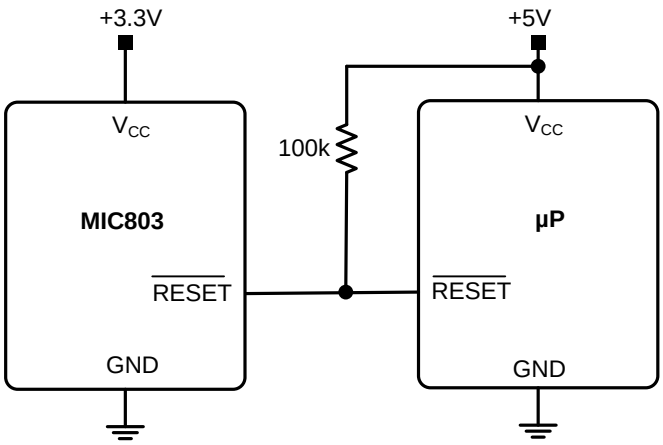

Figure 1. MIC803 Used in a Multiple Supply System

/RESET Valid at Low Voltage

As V_{CC} drops to 0V, the MIC803 will no longer be able to pull the /RESET output low, and the pull-up resistor will pull the output high. The value of the pull-up resistor and the voltage it is connected to will affect the point at which this happens.

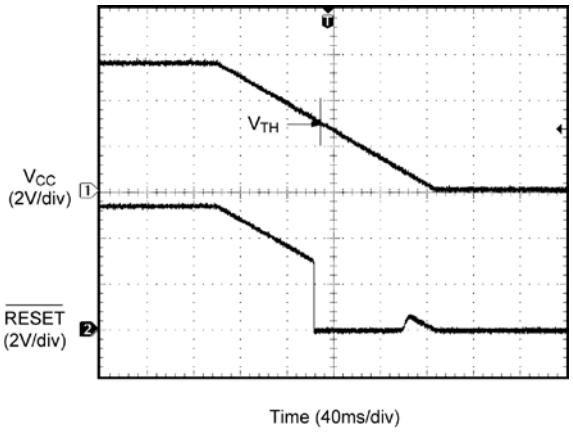

Figure 2. /RESET at Falling V_{CC}

Wire ORing the /RESET Output

Since the /RESET output is open-drain, several reset sources can be wire-ORed, in parallel, to allow resets from multiple sources.

V_{CC} Transients

The MIC803 is relatively immune to negative-going V_{CC} glitches below the reset threshold (see *Typical Characteristics*, graph titled "Maximum Transient Duration vs. Overdrive"). As shown in Figure 3, the overdrive voltage is the difference between the threshold voltage and the minimum point of the V_{CC} glitch. Typically, an overdrive of 100mV, with duration of 15µs or less will not cause a reset. If additional transient immunity is needed, a 0.1µF bypass capacitor can be placed as close as possible to the MIC803 on the VCC pin.
