REVISION HISTORY

4/2017—Rev. B to Rev. C

Changes to AD5932 to 68HC11/68L11 Interface Section 20

11/2016—Rev. A to Rev. B

Changed ADSP-21xx to ADSP-BF527 Throughout

Changes to Features Section 1

Changes to AD5932 to the ADSP-BF527 Interface Section and Figure 34 20

2/2012—Rev. 0 to Rev. A

Changes to Figure 21, Figure 22, Figure 23, Figure 24, and Figure 25 12

Changes to Figure 26, Figure 27, Figure 28, and Figure 29 13

4/2006—Revision 0: Initial Version

GENERAL DESCRIPTION

(continued from Page 1)

To program the [AD5932](#), the user enters the start frequency, the increment step size, the number of increments to be made, and the time interval that the part outputs each frequency. The frequency scan profile is initiated, started, and executed by toggling the CTRL pin.

The [AD5932](#) is written to via a 3-wire serial interface that operates at clock rates up to 40 MHz. The device operates with a power supply from 2.3 V to 5.5 V.

Note that the AVDD and DVDD are independent of each other and can be operated from different voltages. The [AD5932](#) also has a standby function that allows sections of the device that are not in use to be powered down.

The [AD5932](#) is available in a 16-lead, Pb-free TSSOP.

SPECIFICATIONS

AVDD = DVDD = 2.3 V to 5.5 V; AGND = DGND = 0 V; $T_A = T_{MIN}$ to T_{MAX} , unless otherwise noted.

Table 1.

Parameter	Min	Y Grade ¹ Typ	Max	Unit	Test Conditions/Comments
SIGNAL DAC SPECIFICATIONS

¹ Operating temperature range is as follows: Y version: -40°C to +125°C; typical specifications are at +25°C.

² Guaranteed by design, not production tested.

SPECIFICATIONS TEST CIRCUIT

Figure 2. Test Circuit Used to Test the Specifications

TIMING SPECIFICATIONS

All input signals are specified with $t_R = t_F = 5$ ns (10% to 90% of V_{DD}) and are timed from a voltage level of $(V_{IL} + V_{IH})/2$ (see Figure 3 to Figure 6). $DVDD = 2.3$ V to 5.5 V; $AGND = DGND = 0$ V; all specifications T_{MIN} to T_{MAX} , unless otherwise noted.

Table 2.

Parameter ¹	Limit at T_{MIN} , T_{MAX}	Unit	Conditions/Comments
t_1	20	ns min	MCLK period
t_2	8	ns min	MCLK high duration
t_3	8	ns min	MCLK low duration
t_4	25	ns min	SCLK period
t_5	10	ns min	SCLK high time
t_6	10	ns min	SCLK low time
t_7	5	ns min	FSYNC to SCLK falling edge setup time
t_8	10	ns min	FSYNC to SCLK hold time
t_9	5	ns min	Data setup time
t_{10}	3	ns min	Data hold time
t_{11}	$2 \times t_1$	ns min	Minimum CTRL pulse width
t_{12}	0	ns min	CTRL rising edge to MCLK falling edge setup time
t_{13}	$10 \times t_1$	ns typ	CTRL rising edge to VOUT delay (initial pulse, includes initialization)
	$8 \times t_1$	ns typ	CTRL rising edge to VOUT delay (initial pulse, includes initialization)
t_{14}	$1 \times t_1$	ns typ	Frequency change to SYNC output, each frequency increment
t_{15}	$2 \times t_1$	ns typ	Frequency change to SYNC output, end of scan
t_{16}	20	ns max	MCLK falling edge to MSBOUT

¹ Guaranteed by design, not production tested.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 3.

Parameter	Rating
AVDD to AGND	−0.3 V to +6.0 V
DVDD to DGND	−0.3 V to +6.0 V
AGND to DGND	−0.3 V to +0.3 V
CAP/2.5 V to DGND	−0.3 V to +2.75 V
Digital I/O Voltage to DGND	−0.3 V to DVDD + 0.3 V
Analog I/O Voltage to AGND	−0.3 V to AVDD + 0.3 V
Operating Temperature Range	
Automotive (Y Version)	−40°C to +125°C
Storage Temperature Range	−65°C to +150°C
Maximum Junction Temperature	+150°C
TSSOP (4-Layer Board)	
θ_{JA} Thermal Impedance	112°C/W
θ_{JC} Thermal Impedance	27.6°C/W
Reflow Soldering (Pb-Free)	300°C
Peak Temperature	260(+0/−5)°C
Time at Peak Temperature	10 sec to 40 sec

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 7. Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	COMP	DAC Bias Pin. This pin is used for decoupling the DAC bias voltage to AVDD.
2	AVDD	Positive Power Supply for the Analog Section. AVDD can have a value from 2.3 V to 5.5 V. A 0.1 μ F decoupling capacitor should be connected between AVDD and AGND.
3	DVDD	Positive Power Supply for the Digital Section. DVDD can have a value from 2.3 V to 5.5 V. A 0.1 μ F decoupling capacitor should be connected between DVDD and DGND.
4	CAP/2.5V	Digital Circuitry. Operates from a 2.5 V power supply. This 2.5 V is generated from DVDD using an on-board regulator. The regulator requires a decoupling capacitor of typically 100 nF, which is connected from CAP/2.5V to DGND. If DVDD is equal to or less than 2.7 V, CAP/2.5V can be shorted to DVDD.
5	DGND	Ground for All Digital Circuitry.
6	MCLK	Digital Clock Input. DDS output frequencies are expressed as a binary fraction of the frequency of MCLK. The output frequency accuracy and phase noise are determined by this clock.
7	SYNCOUT	Digital Output for Scan Status Information. User-selectable for end of scan (EOS) or frequency increments through the control register (SYNCOPE bit). This pin must be enabled by setting the SYNCOUTEN bit in the control register to 1.
8	MSBOUT	Digital Output. The inverted MSB of the DAC data is available at this pin. This output pin must be enabled by setting the MSBOUTEN bit in the control register to 1.
9	INTERRUPT	Digital Input. This pin acts as an interrupt during a frequency scan. A low-to-high transition is sampled by the internal MCLK, which resets internal state machines. This results in the DAC output going to midscale.
10	CTRL	Digital Input. Triple function pin for initialization, start, and external frequency increments. A low-to-high transition, sampled by the internal MCLK, is used to initialize and start internal state machines, which then execute the pre-programmed frequency scan sequence. When in auto-increment mode, a single pulse executes the entire scan sequence. When in external increment mode, each frequency increment is triggered by low-to-high transitions.
11	SDATA	Serial Data Input. The 16-bit serial data-word is applied to this input with the register address first, followed by the MSB to LSBs of the data.
12	SCLK	Serial Clock Input. Data is clocked into the AD5932 on each falling SCLK edge.
13	FSYNC	Active Low Control Input. This is the frame synchronization signal for the serial data. When FSYNC is taken low, the internal logic is informed that a new word is being loaded into the device.
14	STANDBY	Active High Digital Input. When this pin is high, the internal MCLK is disabled, and the reference DAC and regulator are powered down. For optimum power saving, it is recommended that the AD5932 be reset before it is put into standby, as this results in a shutdown current of typically 20 μ A.
15	AGND	Ground for All Analog Circuitry.
16	VOUT	Voltage Output. The analog outputs from the AD5932 are available here. An external resistive load is not required, because the device has a 200 Ω resistor on board. A 20 pF capacitor to AGND is recommended to act as a low-pass filter and to reduce clock feedthrough.

TERMINOLOGY

Integral Nonlinearity (INL)

Integral nonlinearity is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale and full scale. The error is expressed in LSBs.

Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured and ideal 1 LSB change between two adjacent codes in the DAC. A specified differential nonlinearity of ± 1 LSB maximum ensures monotonicity.

Spurious-Free Dynamic Range (SFDR)

Along with the frequency of interest, harmonics of the fundamental frequency and images of these frequencies are present at the output of a DDS device. The SFDR refers to the largest spur or harmonic that is present in the band of interest. The wideband SFDR gives the magnitude of the largest harmonic or spur relative to the magnitude of the fundamental frequency in the 0 to Nyquist bandwidth. The narrow-band SFDR gives the attenuation of the largest spur or harmonic in a bandwidth of ± 200 kHz about the fundamental frequency.

Total Harmonic Distortion (THD)

Total harmonic distortion is the ratio of the rms sum of harmonics to the rms value of the fundamental. For the [AD5932](#), THD is defined as:

$$THD(\text{dB}) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where:

V_1 is the rms amplitude of the fundamental.

V_2 , V_3 , V_4 , V_5 , and V_6 are the rms amplitudes of the second through the sixth harmonic.

Signal-to-Noise Ratio (SNR)

The signal-to-noise ratio is the ratio of the rms value of the measured output signal to the rms sum of all other spectral components below the Nyquist frequency. The value for SNR is expressed in dB.

Clock Feedthrough

There is feedthrough from the MCLK input to the analog output. Clock feedthrough refers to the magnitude of the MCLK signal relative to the fundamental frequency in the [AD5932](#) output spectrum.

THEORY OF OPERATION

The AD5932 is a general-purpose, synthesized waveform generator capable of providing digitally programmable waveform sequences in both the frequency and time domain. The device contains embedded digital processing to provide a scan of a user-programmable frequency profile allowing enhanced frequency control. Because the device is preprogrammable, it eliminates continuous write cycles from a DSP/microcontroller in generating a particular waveform.

FREQUENCY PROFILE

The frequency profile is defined by the start frequency (F_{START}), the frequency increment (Δf) and the number of increments per scan (N_{INCR}). The increment interval between frequency increments, t_{INT} , is either user-programmable with the interval automatically determined by the device (auto-increment mode), or externally controlled via a hardware pin (external increment mode). For automatic update, the interval profile can be for either a fixed number of clock periods or a fixed number of output waveform cycles.

In the auto-increment mode, a single pulse at the CTRL pin starts and executes the frequency scan. In the external-increment mode, the CTRL pin also starts the scan, but the frequency increment interval is determined by the time interval between sequential 0/1 transitions on the CTRL pin.

An example of a 2-step frequency scan is shown in Figure 30. Note the frequency swept output signal is continuously available and is, therefore, phase continuous at all frequency increments.

Figure 30. Operation of the AD5932

When the AD5932 completes the frequency scan from frequency start to frequency end, that is, from F_{START} incrementally to $(F_{START} + N_{INCR} \times \Delta f)$, it continues to output the last frequency in the scan (see Figure 31). Note that the frequency scan time is given by $(N_{INCR} + 1) \times t_{INT}$.

Figure 31. Frequency Scan

SERIAL INTERFACE

The AD5932 has a standard 3-wire serial interface that is compatible with SPI®, QSPI™, MICROWIRE™, and DSP interface standards.

Data is loaded into the device as a 16-bit word under the control of a serial clock input, SCLK. The timing diagram for this operation is shown in Figure 4.

The FSYNC input is a level-triggered input that acts as a frame synchronization and chip enable. Data can be transferred into the device only when FSYNC is low. To start the serial data transfer, FSYNC should be taken low, observing the minimum FSYNC to SCLK falling edge setup time, t_s . After FSYNC goes low, serial data is shifted into the device's input shift register on the falling edges of SCLK for 16 clock pulses. FSYNC may be taken high after the 16th falling edge of SCLK, observing the minimum SCLK falling edge to FSYNC rising edge time, t_h . Alternatively, FSYNC can be kept low for a multiple of 16 SCLK pulses and then brought high at the end of the data transfer. In this way, a continuous stream of 16-bit words can be loaded while FSYNC is held low. FSYNC should only go high after the 16th SCLK falling edge of the last word is loaded.

The SCLK can be continuous, or, alternatively, the SCLK can idle high or low between write operations.

POWERING UP THE AD5932

When the AD5932 is powered up, the part is in an undefined state and, therefore, must be reset before use. The seven registers (control and frequency) contain invalid data and need to be set to a known value by the user. The control register should be the first register to be programmed, as this sets up the part. Note that a write to the control register automatically resets the internal state machines and provides an analog output of midscale, because it performs the same function as the INTERRUPT pin. Typically, this is followed by a serial loading of all the required scan parameters. The DAC output remains at midscale until a frequency scan is started using the CTRL pin.

PROGRAMMING THE AD5932

The AD5932 is designed to provide automatic frequency scans when the CTRL pin is triggered. The scan is controlled by a set of registers, the addresses of which are given in Table 5. The function of each register is described in more detail in the Setting Up the Frequency Scan section.

The Control Register

The AD5932 contains a 12-bit control register that sets up the operating modes, as shown in the following bit map.

D15	D14	D13	D12	D11 to D0
0	0	0	0	Control bits

This register controls the different functions and the various output options from the AD5932. Table 6 describes the individual bits of the control register.

To address the control register, D15 to D12 of the 16-bit serial word must be set to 0.

Table 5. Register Addresses

Register Address				Mnemonic	Name
D15	D14	D13	D12		
0	0	0	0	C _{REG}	Control bits
0	0	0	1	N _{INCR}	Number of increments
0	0	1	0	Δf	Lower 12 bits of delta frequency
0	0	1	1	Δf	Higher 12 bits of delta frequency
0	1			t _{INT}	Increment interval
1	0				Reserved
1	1	0	0	F _{START}	Lower 12 bits of start frequency
1	1	0	1	F _{START}	Higher 12 bits of start frequency
1	1	1	0		Reserved
1	1	1	1		Reserved

Table 6. Description of Bits in the Control Register

Bit	Name	Function
D15 to D12	ADDR	Register address bits.
D11	B24	Two write operations are required to load a complete word into the F _{START} register and the Δf register. When B24 = 1, a complete word is loaded into a frequency register in two consecutive writes. The first write contains the 12 LSBs of the frequency word and the next write contains the 12 MSBs. Refer to Table 5 for the appropriate addresses. The write to the destination register occurs after both words have been loaded, so the register never holds an intermediate value. When B24 = 0, the 24-bit F _{START} / Δf register operates as two 12-bit registers, one containing the 12 MSBs and the other containing the 12 LSBs. This means that the 12 MSBs of the frequency word can be altered independently of the 12 LSBs and vice versa. This is useful if the complete 24-bit update is not required. To alter the 12 MSBs or the 12 LSBs, a single write is made to the appropriate register address. Refer to Table 5 for the appropriate addresses.
D10	DAC ENABLE	When DAC ENABLE = 1, the DAC is enabled. When DAC ENABLE = 0, the DAC is powered down. This saves power and is beneficial when using only the MSB of the DAC input data (available at the MSBOUT pin).
D9	SINE/TRI	The function of this bit is to control what is available at the VOUT pin. When SINE/TRI = 1, the SIN ROM is used to convert the phase information into amplitude information, resulting in a sinusoidal signal at the output. When SINE/TRI = 0, the SIN ROM is bypassed, resulting in a triangular (up-down) output from the DAC.
D8	MSBOUTEN	When MSBOUTEN = 1, the MSBOUT pin is enabled. When MSBOUTEN = 0, the MSBOUT is disabled (three-state).
D7	Reserved	This bit must be set to 1.
D6	Reserved	This bit must be set to 1.
D5	INT/EXT INCR	When INT/EXT INCR = 1, the frequency increments are triggered externally through the CTRL pin. When INT/EXT INCR = 0, the frequency increments are triggered automatically.
D4	Reserved	This bit must be set to 1.
D3	SYNCSEL	This bit is active when D2 = 1. It is user-selectable to pulse at end of scan (EOS) or at each frequency increment. When SYNCSEL = 1, the SYNCOUT pin outputs a high level at end of scan and returns to 0 at the start of the subsequent scan. When SYNCSEL = 0, the SYNCOUT outputs a pulse of 4 × T _{CLOCK} only at each frequency increment.
D2	SYNCOUTEN	When SYNCOUTEN = 1, the SYNC output is available at the SYNCOUT pin. When SYNCOUTEN = 0, the SYNCOP pin is disabled (three-state).
D1	Reserved	This bit must be set to 1.
D0	Reserved	This bit must be set to 1.

SETTING UP THE FREQUENCY SCAN

As stated in the Frequency Profile section, the AD5932 requires certain registers to be programmed to enable a frequency scan. The Setting Up the Frequency Scan section discusses these registers in more detail.

Start Frequency (F_{START})

To start a frequency scan, the user needs to tell the AD5932 what frequency to start scanning from. This frequency is stored in a 24-bit register called F_{START} . If the user wishes to alter the entire contents of the F_{START} register, two consecutive writes must be performed: one to the LSBs and the other to the MSBs. Note that for an entire write to this register, Control Bit B24 (D11) should be set to 1, with the LSBs programmed first.

In some applications, the user does not need to alter all 24 bits of the F_{START} register. By setting Control Bit B24 (D11) to 0, the 24-bit register operates as two 12-bit registers, one containing the 12 MSBs and the other containing the 12 LSBs. This means that the 12 MSBs of the F_{START} word can be altered independently of the 12 LSBs and vice versa. The addresses of both the LSBs and the MSBs of this register are shown in the following bit map.

D15	D14	D13	D12	D11 to D0
1	1	0	0	12 LSBs of F_{START} <11...0>
1	1	0	1	12 MSBs of F_{START} <23...12>

Frequency Increments (Δf)

The value in the Δf register sets the increment frequency for the scan and is added incrementally to the current output frequency. Note that the increment frequency can be positive or negative, thereby giving an increasing or decreasing frequency scan.

At the start of a scan, the frequency contained in the F_{START} register is output. Next, the frequency ($F_{START} + \Delta f$) is output. This is followed by ($F_{START} + \Delta f + \Delta f$), and so on. Multiplying the Δf value by the number of increments (N_{INCR}) and adding it to the start frequency (F_{START}) give the final frequency in the scan. Mathematically, this final frequency/stop frequency is represented by

$$F_{START} + (N_{INCR} \times \Delta f)$$

The Δf register is a 23-bit register that requires two 16-bit writes to be programmed. Table 7 gives the addresses associated with both the MSB and LSB registers of the Δf word.

Table 7. Δf Register Bits

D15	D14	D13	D12	D11	D10 to D0	Scan Direction
0	0	1	0	12 LSBs of Δf <11...0>		N/A
0	0	1	1	0	11 MSBs of Δf <22...12>	Positive Δf ($F_{START} + \Delta f$)
0	0	1	1	1	11 MSBs of Δf <22...12>	Negative Δf ($F_{START} - \Delta f$)

Number of Increments (N_{INCR})

An end frequency is not required on the AD5932. Instead, this end frequency is calculated by multiplying the frequency increment value (Δf) by the number of frequency steps (N_{INCR}) and adding it to/subtracting it from the start frequency (F_{START}); that is, $F_{START} + N_{INCR} \times \Delta f$. The N_{INCR} register is a 12-bit register, with the address shown in the following bit map.

D15	D14	D13	D12	D11	D0
0	0	0	1	12 bits of N_{INCR}	<11...0>

The number of increments is programmed in binary fashion, with 000000000010 representing the minimum number of frequency increments (two increments) and 111111111111 representing the maximum number of increments (4095).

Table 8. N_{INCR} Data Bits

D11	...	D0	Number of Increments
0000	0000	0010	Two frequency increments. This is the minimum number of frequency increments.
0000	0000	0011	Three frequency increments.
0000	0000	0100	Four frequency increments.
...
1111	1111	1110	4094 frequency increments.
1111	1111	1111	4095 frequency increments.

Increment Interval (t_{INT})

The increment interval dictates the duration of the DAC output signal for each individual frequency of the frequency scan. The AD5932 offers the user two choices:

- The duration is a multiple of cycles of the output frequency.
- The duration is a multiple of MCLK periods.

The desired choice is selected by Bit D13 in the t_{INT} register as shown in the following bit map.

D15	D14	D13	D12	D11	D10 to D0
0	1	0	x	x	11 bits <10...0> Fixed number of output waveform cycles.
0	1	1	x	x	11 bits <10...0> Fixed number of clock periods.

Programming of this register is in binary form, with the minimum number being decimal 2. Note that 11 bits, D10 to D0, of the register are available to program the time interval. As an example, if MCLK = 50 MHz, then each clock period/base interval is (1/50 MHz) = 20 ns. If each frequency must be output for 100 ns, then <00000000101> or decimal 5 must be programmed to this register. Note that the AD5932 can output each frequency for a maximum duration of $2^{11} - 1$ (or 2047) times the increment interval.

Therefore, in this example, a time interval of $20 \text{ ns} \times 2047 = 40 \text{ } \mu\text{s}$ is the maximum, with the minimum being 40 ns . For some applications, this maximum time of $40 \text{ } \mu\text{s}$ may be insufficient. Therefore, to allow for sweeps that need a longer increment interval, time-base multipliers are provided. D12 and D11 are dedicated to the time-base multipliers, as shown in the bit map above. A more detailed table of the multiplier options is given in Table 9.

Table 9. Time-Base Multiplier Values

D12	D11	Multiplier Value
0	0	Multiply (1/MCLK) by 1
0	1	Multiply (1/MCLK) by 5
1	0	Multiply (1/MCLK) by 100
1	1	Multiply (1/MCLK) by 500

If $\text{MCLK} = 50 \text{ MHz}$ and a multiplier of 500 is used, then the base interval (T_{BASE}) is now $(1/(50 \text{ MHz} \times 500)) = 10 \text{ } \mu\text{s}$. Using a multiplier of 500, the maximum increment interval is $10 \text{ } \mu\text{s} \times 2^{11-1} = 20.5 \text{ ms}$. Therefore, the option of time-base multipliers gives the user enhanced flexibility when programming the length of the frequency window, because any frequency can be output for a minimum of 40 ns up to a maximum of 20.5 ms .

The above example shows a fixed number of clock periods. Note that the same equally applies to fixed numbers of clock cycles.

Length of Scan Time

The length of time to complete a user-programmed frequency scan is given by the following equation:

$$T_{\text{SCAN}} = (1 + N_{\text{INCR}}) \times T_{\text{BASE}}$$

ACTIVATING AND CONTROLLING THE SCAN

After the registers have been programmed, a 0 to 1 transition on the CTRL pin starts the scan. The scan always starts from the frequency programmed into the F_{START} register. It changes by the value in the Δf register and increases by the number of steps in the N_{INCR} register. However, the time interval of each frequency can be internally controlled using the t_{INT} register or externally controlled using the CTRL pin. The available options are

- Auto-increment
- External increment

Auto-Increment Control

The value in the t_{INT} register is used to control the scan. The AD5932 outputs each frequency for the length of time programmed in the T_{INT} register, before moving on to the next frequency.

To set up the AD5932 to this mode, INT/EXT INCR (Bit D5) must be set to 0.

External Increment Control

In this case, the time interval, t_{INT} , is set by the pulse rate on the CTRL pin. The first 0 to 1 transition on the pin starts the scan. Each subsequent 0 to 1 transition on the CTRL pin increments the output frequency by the value programmed into the Δf register.

To set up the AD5932 to this mode, INT/EXT INCR (Bit D5) must be set to 1.

INTERRUPT Pin

This function is used as an interrupt during a frequency scan. A low-to-high transition on this pin is sampled by the internal MCLK, thereby resetting internal state machines, which results in the output going to midscale.

STANDBY Pin

Sections of the AD5932 that are not in use can be powered down to minimize power consumption. This is done by using the STANDBY pin. For optimum power savings, it is recommended to reset the AD5932 before entering standby. Doing so reduces the power-down current to $20 \text{ } \mu\text{A}$.

When this pin is high, the internal MCLK is disabled, and the reference, DAC, and regulator are powered down. When in this state, the DAC output of the AD5932 remains at its present value, because the NCO is no longer accumulating. When the device is taken back out of standby mode, the MCLK is re-activated, and the scan continues. To ensure correct operation for new data, it is recommended that the device be internally reset, using a control register write or using the INTERRUPT pin, and then restarted.

OUTPUTS FROM THE AD5932

The AD5932 offers a variety of outputs from the chip. The analog outputs are available from the VOUT pin and include a sine wave and a triangle output. The digital outputs are available from the MSBOUT pin and the SYNCOUT pin.

Analog Outputs

Sinusoidal Output

The SIN ROM is used to convert the phase information from the frequency register into amplitude information, resulting in a sinusoidal signal at the output.

The AD5932 includes a 10-bit, high impedance, current source DAC that is configured for single-ended operation. An external load resistor is not required because the device has a 200 Ω resistor on board. To have a sinusoidal output from the VOUT pin, set SINE/TRI (Bit D9) in the control register to 1.

Triangle Output

The SIN ROM can be bypassed so that the truncated digital output from the NCO is sent to the DAC. In this case, the output is no longer sinusoidal. The DAC produces a 10-bit linear triangular function. To have a triangle output from the VOUT pin, set SINE/TRI (Bit D9) to 0. Note that DAC ENABLE (Bit D10) must be set to 1 (that is, the DAC is enabled) when using this pin.

Figure 32. Triangle Output

Digital Outputs

Square-Wave Output from MSBOUT

The inverse of the MSB from the NCO can be output from the AD5932. By setting MSBOUTEN (Bit D8) to 1, the inverted MSB of the DAC data is available at the MSBOUT pin. This is useful as a digital clock source.

Figure 33. MSB Output

SYNCOUT Pin

The SYNCOUT pin can be used to give the status of the scan. It is user-selectable for the end of scan or to output a $4 \times T_{\text{CLOCK}}$ pulse at frequency increments. The timing information for both of these modes is shown in Figure 6.

The SYNCOUT pin must be enabled before use. This is done using Bit D2 in the control register. The output available from this pin is then controlled by Bit D3 in the control register. See Table 6 for more information.

APPLICATIONS INFORMATION

GROUNDING AND LAYOUT

The printed circuit board that houses the AD5932 should be designed so that the analog and digital sections are separated and confined to certain areas of the board. This facilitates the use of ground planes that can be easily separated. A minimum etch technique is generally best for ground planes because it gives the best shielding. Digital and analog ground planes should be joined in only one place. If the AD5932 is the only device requiring an AGND-to-DGND connection, then the ground planes should be connected at the AGND and DGND pins of the AD5932. If the AD5932 is in a system where multiple devices require AGND-to-DGND connections, the connection should be made at one point only, a star ground point that should be established as close as possible to the AD5932.

Avoid running digital lines under the device because these couple noise onto the die. The analog ground plane should run under the AD5932 to avoid noise coupling. The power supply lines to the AD5932 should use as large a track as possible to provide low impedance paths and reduce the effects of glitches on the power supply line. Fast switching signals, such as clocks, should be shielded with digital ground to avoid radiating noise to other sections of the board. Avoid crossover of digital and analog signals. Traces on opposite sides of the board should run at right angles to each other, reducing the effects of feedthrough. A microstrip technique is by far the best but is not always possible with a double-sided board. In this technique, the component side of the board is dedicated to ground planes, while signals are placed on the other side.

Good decoupling is important. The analog and digital supplies to the AD5932 are independent and separately pinned out to minimize coupling between analog and digital sections of the device. All analog and digital supplies should be decoupled to AGND and DGND, respectively, with 0.1 μ F ceramic capacitors in parallel with 10 μ F tantalum capacitors. To achieve the best from the decoupling capacitors, they should be placed as close as possible to the device, ideally right up against the device. In systems where a common supply is used to drive both the AVDD and DVDD of the AD5932, it is recommended that the system's AVDD supply be used. This supply should have the recommended analog supply decoupling between the AVDD pin of the AD5932 and AGND and the recommended digital supply decoupling capacitors between the DVDD pin and DGND.

Interfacing to Microprocessors

The AD5932 has a standard serial interface that allows the part to interface directly with several microprocessors. The device uses an external serial clock to write the data/control information into the device. The serial clock can have a frequency of 40 MHz maximum. The serial clock can be continuous, or it can idle high or low between write operations.

When data/control information is being written to the AD5932, FSYNC is taken low and is held low while the 16 bits of data are being written into the AD5932. The FSYNC signal frames the 16 bits of information being loaded into the AD5932.

AD5932 TO THE ADSP-BF527 INTERFACE

Figure 34 shows the serial interface between the AD5932 and the ADSP-BF527. The serial port (SPORT) of the ADSP-BF527 processor must be set up to operate in the DSP serial mode. The data is clocked out on each rising edge of the serial clock and clocked into the AD5932 on the SCLK falling edge.

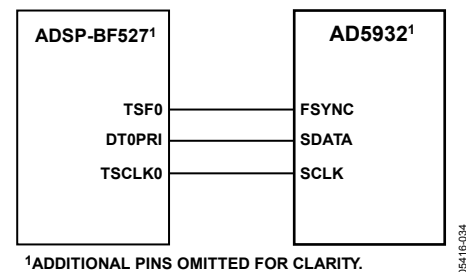

Figure 34. ADSP-BF527 to AD5932 Interface

AD5932 TO 68HC11/68L11 INTERFACE

Figure 35 shows the serial interface between the AD5932 and the 68HC11/68L11 microcontroller. The microcontroller is configured as the master by setting Bit MSTR in the SPCR to 1, which provides a serial clock on SCK while the MOSI output drives the serial data line, SDATA. Because the microcontroller does not have a dedicated frame sync pin, the FSYNC signal is derived from a port line (PC7). The set-up conditions for correct operation of the interface are as follows:

- SCK idles high between write operations (CPOL = 1).
- Data is valid on the SCK falling edge (CPHA = 0).

When data is being transmitted to the AD5932, the FSYNC line is taken low (PC7). Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. In order to load data into the AD5932, PC7 is held low after the first eight bits are transferred and a second serial write operation is performed to the AD5932. Only after the second eight bits have been transferred should FSYNC be taken high again.

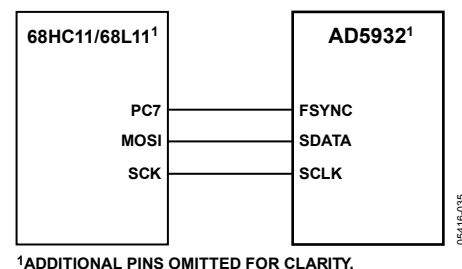

Figure 35. 68HC11/68L11 to AD5932 Interface

AD5932 TO 80C51/80L51 INTERFACE

Figure 36 shows the serial interface between the AD5932 and the 80C51/80L51 microcontroller. The microcontroller is operated in Mode 0 so that TxD of the 80C51/80L51 drives SCLK of the AD5932, while RxD drives the serial data line SDATA. The FSYNC signal is again derived from a bit programmable pin on the port (P3.3 being used in the diagram). When data is to be transmitted to the AD5932, P3.3 is taken low. The 80C51/80L51 transmits data in 8-bit bytes; thus, only eight falling SCLK edges occur in each cycle.

To load the remaining eight bits to the AD5932, P3.3 is held low after the first eight bits have been transmitted, and a second write operation is initiated to transmit the second byte of data. P3.3 is taken high following completion of the second write operation. SCLK should idle high between the two write operations. The 80C51/80L51 outputs the serial data in an LSB-first format. The AD5932 accepts the MSB first (the four MSBs being the control information, the next four bits being the address, while the eight LSBs contain the data when writing to a destination register). Therefore, the transmit routine of the 80C51/80L51 must consider this and rearrange the bits so that the MSB is output first.

Figure 36. 80C51/80L51 to AD5932 Interface

AD5932 TO DSP56002 INTERFACE

Figure 37 shows the interface between the AD5932 and the DSP56002. The DSP56002 is configured for normal mode, asynchronous operation with a gated internal clock (SYN = 0, GCK = 1, SCKD = 1). The frame sync pin is generated internally (SC2 = 1), the transfers are 16 bits wide (WL1 = 1, WL0 = 0), and the frame sync signal frames the 16 bits (FSL = 0). The frame sync signal is available on Pin SC2, but it must be inverted before being applied to the AD5932. The interface to the DSP56000/DSP56001 is similar to that of the DSP56002.

EVALUATION BOARD

The [AD5932](#) evaluation board allows designers to evaluate the high performance [AD5932](#) DDS modulator with minimum effort.

The evaluation board interfaces to the USB port of a PC. It is possible to power the entire board from the USB port. All that is needed to complete the evaluation of the chip is either a spectrum analyzer or a scope.

The DDS evaluation kit includes a populated and tested [AD5932](#) printed circuit board. The [EVAL-AD5932EB](#) kit is shipped with a CD-ROM that includes self-installing software. The PC is connected to the evaluation board using the supplied cable. The software is compatible with Microsoft® Windows® 2000 and Windows XP.

A schematic of the evaluation board is shown in Figure 38 and Figure 39.

Using the [AD5932](#) Evaluation Board

The [AD5932](#) evaluation kit is a test system designed to simplify the evaluation of the [AD5932](#). An application note is also available with the evaluation board that gives full information on operating the evaluation board.

Prototyping Area

An area is available on the evaluation board for the user to add additional circuits to the evaluation test set. Users may want to build custom analog filters for the output or add buffers and operational amplifiers to be used in the final application.

XO vs. External Clock

The [AD5932](#) can operate with master clocks up to 50 MHz. A 50 MHz oscillator is included on the evaluation board. However, this oscillator can be removed and, if required, an external CMOS clock can be connected to the part.
