Functional Description

The A5932 targets high speed server fan applications to meet the objectives of low audible noise, minimal vibration, and high efficiency. Allegro's proprietary control algorithm results in a sinusoidal current waveshape that adapts to a variety of motor characteristics to dynamically optimize efficiency across a wide range of speeds.

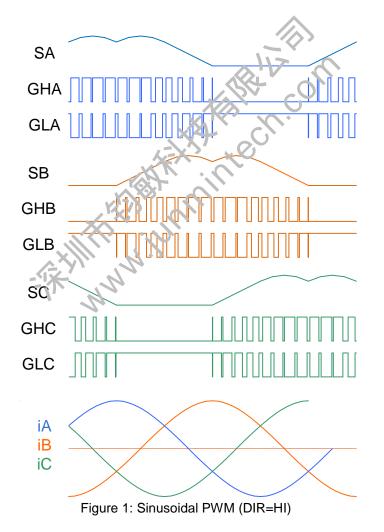

The speed of the fan is controlled by variable duty cycle PWM input.

The PWM input duty is measured and converted to a 9bit number. This 9 bit "demand" is applied to a pwm generator block to create the modulation profile. The

modulation profile is applied to the three motor outputs, with 120 degree phase relationship, to create the sinusoidal current waveform as shown in Figure 1.

Protection features include lock detection with restart, motor output short circuit, supply undervoltage monitor and thermal shutdown.

Standby mode can be achieved by holding SPD pin low for longer than the programmed Lock off-time. In specific speed curve options, the motor will never turn off with 0% duty cycle applied. In this type of configuration, standby mode is not available.

Functional Description

VREF. Voltage reference (2.8V) to power internal digital logic and analog circuitry. V_{REF} can be used to power external circuitry with up to 20mA bias current if desired. Stabilize with .1uF or greater ceramic capacitor.

FG. Open drain output provides speed information to the system. The open drain output can be pulled up to V_{REF} or external 3.3 or 5V supply.

RD.

Open drain output, Logic high indicates a rotor fault condition as defined by EEPROM variables. RD function can be disabled via EEPROM. When function is disabled RD pin low to high transition indicates end of open loop starting sequence.

BRAKE. Active High signal turns on all low sides for braking function. Brake Function will prevent IC from entering standby mode. Brake function overrides Speed control input. Care should be taken to avoid stress on the MOSFET when braking while motor is running. With braking the current will be limited by V_{BEMF}/R_{MOTOR}.

DIR. Logic Input to control motor direction. For logic high, motor phases are ordered $A \rightarrow B \rightarrow C$. For logic low $A \rightarrow C \rightarrow B$. If Direction input is changed while motor running, motor will coast for a duration defined by T_Coast. After this delay, motor will then attempt to restart in desired direction.

ISET. A resistor (R_{ISET}) to GND sets the magnitude of gate current. The sink and source current ratios are fixed at approximately 2:1. Resistor value RISET should be in the range 15K to 150K.

The formula for gate drive current is as follows:

$$\begin{split} I_{GATE_SRC}(mA) &= 1.9 + 900/R_{ISET} \, (Kohms) \\ I_{GATE_SNK}(mA) &= 3.5 + 1700/R_{ISET} \, (Kohms) \end{split}$$

If pin ISET is connected to GND, the circuit will default to a level equivalent to 30K. If ISET is open, the motor outputs will be disabled.

CTAP. This analog input is an optional connection for motor common (Wye motors). If not used, as in case of Delta wound motor, then pin must be left open circuit. Speed

SPD. Speed Demand input pin. Choice of analog voltage control or PWM duty control is determined by EEPROM selection.

Duty cycle control. The PWM frequency must be in the range 100Hz to100kHz. Duty cycle resolution is 9Bit.

Analog control. Voltage applied will increase speed demand. An internal 9 bit A/D converter will translate the input to a speed demand.

Standby Mode. A low power mode is activated if SPD pin is held low. Standby Mode will turn off all circuitry including charge pump and VREF. Upon power up, the A5932 will immediately wake up. If SPD remains low for the programmed lock time, standby mode will be activated. Standby mode can be disabled via EEPROM bit.

Lo: Contect. A logic circuit monitors the motor position to determine it motor is running as expected. If a fault is detected, the motor drive will be disabled for T_{LOCK} before an auto-restart is attempted.

Current Limit. Maximum load current can be set by choice of external sense resistor connected between LSS terminal and GND.

ILIM = 250mV/RSENSE

Preliminary Datasheet

Downloaded from Arrow.com.

nFAULT. The following signals will bring output nFAULT low:

- 1) VBB Undervoltage
- 2) Thermal Shutdown
- 3) Charge Pump UVLO
- 4) VBB Overvoltage
- 5) Output Vds Fault (OCP)
- 6) Loss of synchronization

Fault	Fault Action	Latched	Readback Reg[Bit]
Vbb Undervoltage	Disable Outputs	N	147[8]
TSD	Disable Outputs	N	147[6]
Charge Pump	Disable Outputs	N	147[7]
Vbb Overvoltage	Disable Outputs or disabled outputs and set Lock detect	N	147[9]
VDS Fault	Choose by EEPROM bit OCPOPT	If OCPOP=1	147[5:0]
Loss of Sync	Set Lock detect timeout	N	148[6:0]

<u>.....</u>

Speed Control Options.

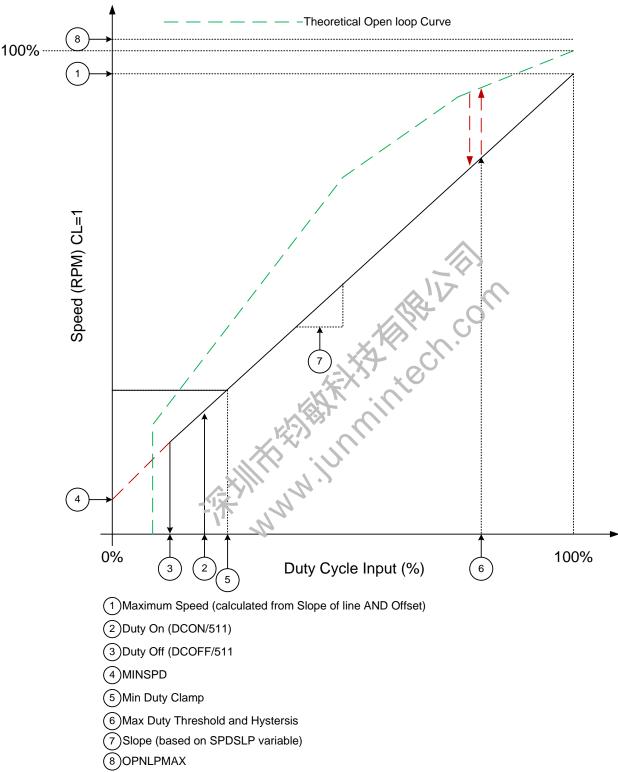

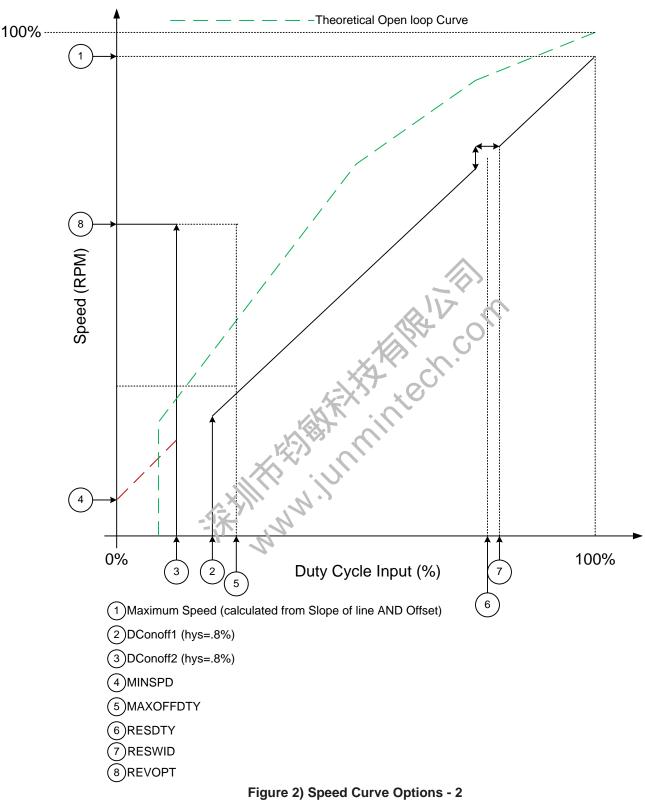

Figure 1) Speed Curve Options

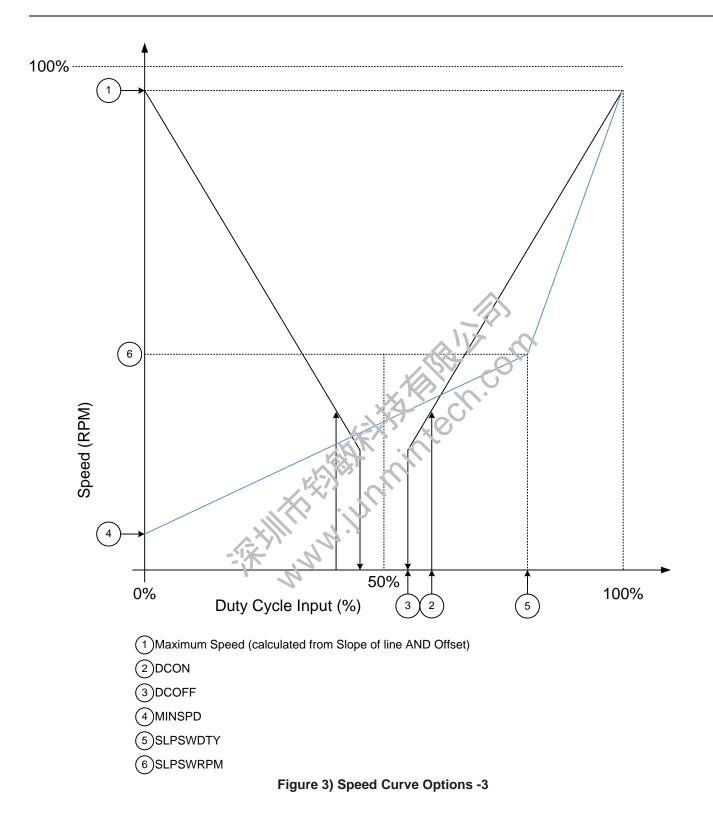

Preliminary Datasheet

9

Speed Curve Parameters (continued)

Refer to Figure 1-3 for below items.

Minimum Speed Set point.

The minimum speed is defined by the value stored in EEPROM variable MINSPD. The resolution is 1RPM.

MINSPD (RPM) = 0..4095

Maximum Speed Set point.

The A5932 calculates the maximum speed based on line equation y=mx + B. The maximum speed is defined as the speed with input duty = 100%.

The desired maximum speed is used to set the EEPROM variable SPDSLP.

SPDSLP = 64*(Maximum Speed (Rpm) - MINSPD)/511

Example: Max Speed = 25000, Min Speed = 3000.

SPDSLP = 64*22000/511 = 2755

Where SPDSLP = 0..16383

Motor Speed (RPM) = Slope*DutyIN + MINSPD.

Where Slope = SPDSLP*511/64 and DutyIN expresse in %.

Duty In Enable Threshold.

EEPROM variable DCON defines the input duty signal that enables the drive. DCON is a 8 bit number with resolution of .2%, which results in a ritex setting of 49.9%.

Duty On (%) = 100*DCON/511

If DCON is set to "0", motor will turn on with 0% duty cycle input.

Duty In Disable Threshold.

EEPROM variable DCOFF defines the input duty signal that disables the drive. DCOFF is an 8 bit number with resolution of .2%, which results in a max setting of 49.9%.

Duty Off(%) = DCOFF/511

DCOFF should always be set to a lower number than DCON.

ON/Off Control Option.

If bit ONOFFCNTRL bit is set to "1" then the motor will runs off if duty is between the values set by DCON & DCOFF. A fixed value of .8% hysteresis is applied. In this option, if the duty is below DCOFF, then the motor will be enabled with a PWM level set by variable MAXDTYOFF. (see figure 2)

Additionally, if duty is below DCOFF, the motor direction can be made to be reverse if REVOPT is set to "1".

Duty Cycle Invert.

To create mirror image of speed curve, set Duty cycle invert bit to "1".

Minimum Duty Clamp.

Minimum speed can be clamped to a value to allow motor to run at defined low level speed. This is achieved by ignoring the duty cycle input if below the programmed MINDTY level.

Mir. Duty Clamp (%) = 100*MINDTY/511

hterefore the minimum speed will be defined by:

MinSceedClamp(RPM) = Slope*MinDutyClamp+MINSPD

Setting MINDTY to 0 disables the function.

MINDTY=0..255

Downloaded from Arrow.com.

To avoid any issues with mechanical resonance at a particular

speed band, variable RESWID & RESDTY are provided to

RESWID: defines width of band relative to center duty value

When the speed curve is set to open loop mode it is possible

to limit the speed to prevent fan speed overshoot. Rpm is monitored and the demand will be clamped at level that results

OPNLPMAX variable has no effect in closed loop mode.

RESDTY: defines duty cycle that is center of band

Resonance Option. (see figure 3)

Open Loop Maximum Limit

in max limit.

allow skipping over a defined RPM and.

Maximum Duty Clamp.

EEPROM variable DTYMAX defines a duty level at which the motor will change operation from closed loop curve. The change of operation would depend on MAXDTYOPT setting. If MAXDTYOP = 0, open loop operation will result, if MAXDTYOPT = 1 then operation will remain closed loop however the speed will be clamped at the value calculated by DTYMAX level.

4 bits are used for this setting at resolution of 1.6% to cover the range 76.5% to 100%.

Maximum Duty (%) = 100*(511-MAXDTY*8)/511

MAXDTY = 0..15; If MAXDTY=0 then function is disabled.

Hysteresis is needed to prevent motor from going back and forth between open and closed loop mode.

MAXDTYHYS = 0...15

 $Hys(\%) = (MAXDTYHYS+1)^*.4$

50% Duty Option.

netions the management of the contractions of the contraction of the c If bit DIR50 is set to 1, the motor direction can be controlled by duty cycle level. (see figure 3) For this setting, the motor enable and disable functions will be set by:

DCONnew = 50% +/- DCON DCOFFnew = 50% +/-DCOFF

Since the duty cycle reference changes from 190% scale to 50% scale. The slope of the curve is now 2% compared to normal (DIR50=0) setting. When duty changes to switch direction, the motor will coast for time programmed via TCOAST variable before attempting to startup in opposite direction. Care should be taken to minimize stress on the MOSFETS when switching direction.

Dual Slope Option. (see figure 3) Two different slopes can be selected by setting variable SLPSWDTY greater than 0.

Slope2 = (MAXSPEED-SLPSWRPM)/(100%-SLPSWDTY)

Slope1 = (SLPSWRPM – MINSPEED)/SLPSWDTY

Preliminary Datasheet

High-Performance Semiconductors

Serial Port Control Option

Normally the IC is controlled by duty cycle input and uses the EEPROM data that is stored to create the speed curve profile (as show in Figure xx). However, it is possible to use direct serial port control to avoid programming EEPROM. When using direct control, the input duty cycle command is replaced by writing to a 9 bit number to register 165.

Example: REGADDR[data]: (in decimal) 165[511] → Duty=100% 165[102] → Duty=102/511=20%

Upon power up, IC defaults to duty cycle input mode. To use serial port mode, the internal registers should be programmed before turning the part on. The sequence to use serial port mode is:

- 1) Drive FG & SPD pins low**
- 2) Power up IC
- 3) Program registers for parameter setting that correspond to each of the EEPROM memory locations.
 - a. REGADDR = 64 + EEPROM ADDR.
 - b. Program register addresses 65 to 84 corresponding to EEPROM addresses 1 to 20
 - It may be helpful to use the GUI text file to help define the hex data for each of the EEPROM C. addresses.
- 4) Write to register 165 to start motor

, to start im, **Note: If SPD is not driven low before power up, motor will try to star immediately as the default high value will demand 100% on signal.

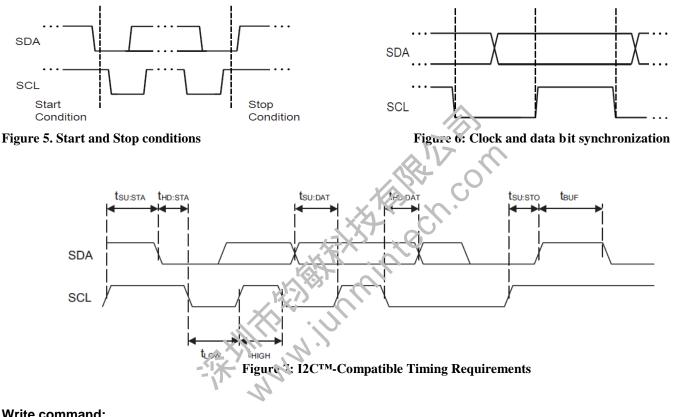

Serial Port.

The A5931 uses standard fast mode I2C serial port format to program the EEPROM or to control the IC speed serially. The SPD pin functions as the clock (SCL) input, and the FG pin is the data line (SDA). No special sequence is needed to begin transferring data. If the motor is running the FG may pull then data line low while trying to initialize into serial port mode. Once an I2C command is sent the SPD input is ignored, and the motor will turn off as if a PWM duty command of 0% was sent.

The 5931 7 bit slave address is 0x55).

I²C Timing Diagrams.

Write command:

- 1) Start Condition
- 7 bit I2C Slave Address (Device ID) 1010101, R/W Bit = 0 2)
- 3) Internal Register Address
- 4) 2 data bytes, MSB first
- Stop Condition 5)

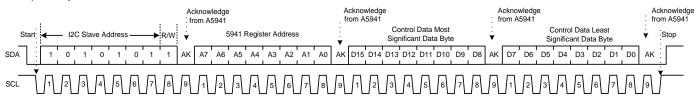

Figure 8: Write Command

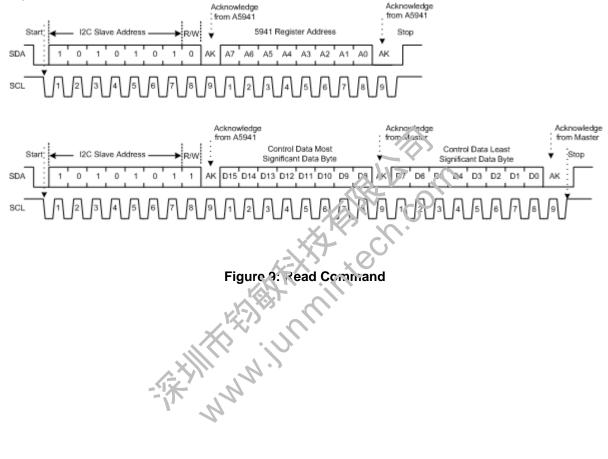

17

Read command: Two Step Process

- 1) Start Condition
- 2) 7 bit I2C Slave Address (Device ID) 1010101, R/W Bit = 0
- 3) Internal Register Address to be read
- 4) Stop Condition
- 5) Start Condition
- 6) 7 bit I2C Slave Address (Device ID) 1010101, R/W Bit = 1
- 7) Read 2 data bytes
- 8) Stop Condition

Programming EEPROM. The A5931 contains 24words of 16 bit length. The EEPROM is controlled with the following i2c registers. Refer to application note for EEPROM definition.

EEP	EEPROM Control – Register 161. Used to control programming of EEPROM															
15	5 14		13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0		0	0	0	0	0	0	0	0	0	0	RD	WR	ER	EN

EEPROM Control -	Register 161	· I lead to cont	trol programming	
	- Register IDI		li ol programming	

Name	scription							
EN	Set EEProm Voltage required for Writing or Erasing							
ER	Sets Mode to Erase							
WR	Sets Mode to Write							
RD	Sets Mode to Read							
n/a	Do not use, always set to Zero during programming process							
	EN ER WR RD							

EEPROM Address- Register 162: Used to set the EEPROM address to be altered

15	14	13	12	11	10	9	8	7	\$	5	6	3	2	1	0	
0	0	0	0	0	0	0	0	0)	0		eeADDRESS				

Bit	Name	Description
0	eeADDRESS	Used to specify EEPROM address to be changed. There are 20 addresses. Do not change address 0 or 19 as these are factory controlled
15:5	n/a	Do not use always set to Zero during programming process

EEPROM DataIn - Register 163: Used to set the EEPROM new data to be programmed

15	14	13	12	11 10	9 8	7	6	5	4	3	2	1	0
	eeDATAin												

Bit	Name	Description					
15:0	eeDATAin	Used to specify the new EEPROM data to be changed.					

EEPRO	EEPROM DataOUT – Register 164: Used for read operations.														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	eeDATAout														

Bit	Name	Description					
15:0	eeDATAout	Used to readback EEPROM data from address defined in register 162					

There are 3 basic commands, Read, Erase, and Write. To change the contents of a memory location, the word must be first erased. The EEPROM programming process (writing or erasing) takes 10ms per word. Each word must be written individually.

Example #1: Write EEPROM address 5 to 261 (hex=0x0105)

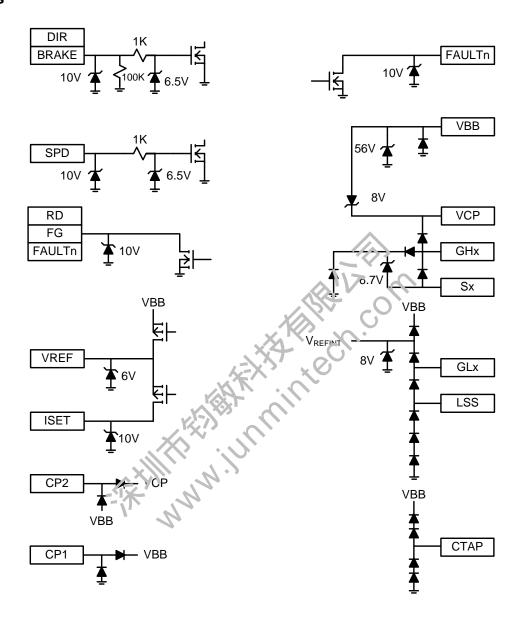

1) Erase the word

	Elase		
		I2c Write REGAD	DR[Data] ; comment
	а.	162[5]	; set EEPROM address to erase
	b.	163[0]	; set 0000 as Data In 💦 📉 💙
	C.	161[3]	; set control to Erase and Voltage High
	d.	Wait 15ms	; requires 15ms Hig/ Voltage Pulse to Write
	e.	161[0]	; clear Voltage
2)	Write t	he new data	
	а.	162[5]	; set EEPROW address to write
	b.	163[261]	; set Data In - 261
	C.	161[5]	; set control to Write and Set Voltage High
	d.	Wait 15ms	; requires 15ms High Voltage Pulse to Write
	e.	161[5]	: clear Voltage
Exam	ple #2 R	ead address 5 to co	onfirm correct data properly programmed.
1)		he word	
	а.	5[i2c read]	: read register 5; this will be contents of EEPROM
			V

- 1) Read the word
 - a. 5[i2c read]
