PIN FUNCTIONS

GND (Pin 1): Signal Ground. Tie to PGND under the package.

LBO (Pin 2): Open-Collector Output of Low-Battery Comparator. Can sink 100 μ A. Disabled when device is in shutdown.

SHDN (Pin 3): Shutdown. Pull high to shut down the device. Ground for normal operation.

FB/Sense (Pin 4): On 1303 (adjustable) this pin connects to the main comparator C1 input. On LT1303-5 this pin connects to the resistor string that sets output voltage at 5V.

LBI (Pin 5): Low-Battery Comparator Input. When voltage on this pin below 1.24V, LBO is low.

V_{IN} (Pin 6): Supply Pin. Must be bypassed with a large value electrolytic to ground. Keep bypass within 0.2" of the device.

SW (Pin 7): Switch Pin. Connect inductor and diode here. Keep layout short and direct to minimize radio frequency interference.

PGND (Pin 8): Power ground. Tie to signal ground (pin1) under the package. Bypass capacitor from V_{IN} should be tied directly to PGND within 0.2" of the device.

BLOCK DIAGRAMS

BLOCK DIAGRAMS

Figure 3. LT1303-5 Block Diagram

LT1303 B002

OPERATION

Operation of the LT1303 is best understood by referring to the Block Diagram in Figure 2. When C1's negative input, related to the output voltage by the appropriate resistor-divider ratio, is higher than the 1.24V reference voltage, C1's output is low. C2, A3 and the oscillator are turned off, drawing no current. Only the reference and C1 consume current, typically 140μA. When C1's negative input drops below 1.24V and overcomes C1's 6mV hysteresis, C1's output goes high, enabling the oscillator, current comparator C2 and driver A3. Quiescent current increases to 2mA as the device goes into active switching mode. Q1 then turns on in controlled saturation for nominally 6μs or until current comparator C2 trips, whichever comes first. The switch then turns off for approximately 1.5μs, then turns on again. The LT1303's switching causes current to alternately build up in L1 and dump into output capacitor C4 via D1, increasing the output voltage. When the output is high enough to cause C1's output to go high, switching action ceases. Capacitor C4 is left to supply current to the load until V_{OUT} decreases enough to force C1's output high, and the entire cycle repeats. Figure 4 details relevant waveforms. C1's cycling causes low-to-mid-frequency ripple voltage on the output. Ripple can be reduced by making the

output capacitor large. The 100μF unit specified results in ripple of 50mV to 100mV on the 5V output. A 220μF capacitor will decrease ripple by approximately 50%.

Figure 4. Burst Mode Operation in Action

If switch current reaches 1A, causing C2 to trip, switch on-time is reduced and off-time increases slightly. This allows continuous operation during bursts. C2 monitors the voltage across 3Ω resistor R1 which is directly related to the switch current. Q2's collector current is set by the emitter-area ratio to 0.6% of Q1's collector current. When R1's voltage drop exceeds 18mV, corresponding to 1A switch current, C2's output goes high, truncating the on-time portion of the oscillator cycle and increasing off-time

OPERATION

to about 2μs. Response time of C2, which determines minimum on-time, is approximately 300ns.

Low Battery Detector

The low battery detector is enabled when SHDN is low and disabled when SHDN is high. The comparator has no

Figure 5. R3 Adds Hysteresis to Low-Battery Detector

hysteresis built in, but hysteresis can be added by connecting a high-value resistor from LBI to LBO as shown in Figure 5. The internal reference can be accessed via the comparator as shown in Figure 6.

Figure 6. Accessing Internal Reference

APPLICATIONS INFORMATION

Inductor Section

Inductors suitable for use with the LT1303 usually fall in the 5μH to 50μH range. The inductor must: (1) handle current of 1.25A without saturating, (2) have enough inductance to provide a di/dt lower than 400mA/μs, and (3) have low enough DC resistance to avoid excessive heating or efficiency losses. Higher value inductors will deliver more power but tend to be physically larger. Most ferrite core drum or rod inductors such as those specified in Table 1 are suitable for use. It is acceptable to bias open-flux inductors (e.g. Sumida CD54) into saturation by 10 to 20% without adverse effects.

Table 1. Recommended Inductors

VENDOR	SERIES	APPROPRIATE VALUES	PHONE NUMBERS
Coilcraft	D03316 D01608	10μH to 47μH 10μH	(708) 639-6400
Coiltronics	OCTAPAK CTX20-1 CTX20-2 CTX33-4	20μH 20μH 33μH	(407) 241-7876
Sumida	CD54	10μH to 33μH	(708) 956-0666
Gowanda	GA10	10μH to 33μH	(716) 532-2234

Figure 7 shows inductor current of a suitable inductor, di/dt is controlled at all times. The rapid rise in current shown in Figure 8 results from this inductor saturating at approximately 1A. Saturation occurs when the inductor cannot hold any more magnetic energy in the core. Current then increases rapidly, limited only by the resistance of the winding. Figure 9's inductor has high DC resistance which results in the exponential time constant shape of the inductor current.

Figure 7. Properly Chosen Inductor Does Not Saturate

APPLICATIONS INFORMATION

Figure 9. Slight Exponential Shape to Inductor Current Waveform Indicates Excessive DC Resistance

Diode Selection

The LT1303’s high switching speed demands a high speed rectifier. Schottky diodes are preferred for their low forward drop and fast recovery. Suitable choices include the 1N5817, MBRS120LT3, and MBR0520LT1. Do not use signal diodes such as 1N4148. They cannot carry 1A current. Also avoid “general-purpose” diodes such as 1N4001. These are far too slow and are unsuitable for any switching regulator application. For high temperature applications a silicon diode such as the MUR105 will have less leakage.

Capacitor Selection

Input and output capacitors should have low ESR for best efficiency. Recommended capacitors include AVX TPS series, Sprague 595D series, and Sanyo OS-CON. The output capacitor’s ESR determines the high frequency ripple amplitude. A 100 μ F capacitor is the minimum recommended for a 5V output. Higher output voltages can use lower capacitance values. For example, a 12V output can use a 33 μ F or 47 μ F capacitor. The V_{IN} pin of the LT1303 should be decoupled with a 47 μ F or 100 μ F capacitor at the pin. When driving a transformer, an additional decoupling network of 10 Ω and 0.1 μ F ceramic is recommended as shown in Figure 10.

Figure 10. 10 Ω -1 μ F Network to LT1303 V_{IN} Pin Provides Additional Decoupling. Recommended When Driving Transformers.
