Time 25°C to Peak Temperature	8 min

¹ Digital inputs are protected; however, permanent damage can occur on unprotected units from high energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.

² Remove power before inserting or removing units from their sockets.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions, that is, a device in socket.

Table 3. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
TO-92 (T-3-1)	162	120	°C/W
SOIC_N (R-8)	158	43	°C/W
SOT-23 (RJ-5)	300	180	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

FUNCTIONAL DESCRIPTION

An equivalent circuit for the **TMP35/TMP36/TMP37** micropower, centigrade temperature sensors is shown in Figure 22. The core of the temperature sensor is a band gap core that comprises transistors Q1 and Q2, biased by Q3 to approximately 8 μ A. The band gap core operates both Q1 and Q2 at the same collector current level; however, because the emitter area of Q1 is 10 times that of Q2, the V_{BE} of Q1 and the V_{BE} of Q2 are not equal by the following relationship:

$$\Delta V_{BE} = V_T \times \ln \left(\frac{A_{E,Q1}}{A_{E,Q2}} \right)$$

Resistors R1 and R2 are used to scale this result to produce the output voltage transfer characteristic of each temperature sensor and, simultaneously, R2 and R3 are used to scale the V_{BE} of Q1 as an offset term in V_{OUT} . Table 4 summarizes the differences in the output characteristics of the three temperature sensors.

The output voltage of the temperature sensor is available at the emitter of Q4, which buffers the band gap core and provides load current drive. The current gain of Q4, working with the available base current drive from the previous stage, sets the short-circuit current limit of these devices to 250 μ A.

Figure 22. Temperature Sensor Simplified Equivalent Circuit

Table 4. **TMP35/TMP36/TMP37** Output Characteristics

Sensor	Offset Voltage (V)	Output Voltage Scaling (mV/°C)	Output Voltage at 25°C (mV)
TMP35	0	10	250
TMP36	0.5	10	750
TMP37	0	20	500

APPLICATIONS INFORMATION

SHUTDOWN OPERATION

All TMP35/TMP36/TMP37 devices include a shutdown capability, which reduces the power supply drain to less than 0.5 μA maximum. This feature, available only in the SOIC_N and the SOT-23 packages, is TTL/CMOS level-compatible, provided that the temperature sensor supply voltage is equal in magnitude to the logic supply voltage. Internal to the TMP35/TMP36/TMP37 at the SHUTDOWN pin, a pull-up current source to $+V_s$ is connected. This allows the SHUTDOWN pin to be driven from an open-collector/drain driver. A logic low, or zero-volt condition, on the SHUTDOWN pin is required to turn off the output stage. During shutdown, the output of the temperature sensors becomes high impedance where the potential of the output pin is then determined by external circuitry. If the shutdown feature is not used, it is recommended that the SHUTDOWN pin be connected to $+V_s$ (Pin 8 on the SOIC_N; Pin 2 on the SOT-23).

The shutdown response time of these temperature sensors is shown in Figure 14, Figure 15, and Figure 16.

MOUNTING CONSIDERATIONS

If the TMP35/TMP36/TMP37 temperature sensors are thermally attached and protected, they can be used in any temperature measurement application where the maximum temperature range of the medium is between -40°C and $+125^\circ\text{C}$. Properly cemented or glued to the surface of the medium, these sensors are within 0.01°C of the surface temperature. Caution should be exercised, especially with T-3 packages, because the leads and any wiring to the device can act as heat pipes, introducing errors if the surrounding air-surface interface is not isothermal. Avoiding this condition is easily achieved by dabbing the leads of the temperature sensor and the hookup wires with a bead of thermally conductive epoxy. This ensures that the TMP35/TMP36/TMP37 die temperature is not affected by the surrounding air temperature. Because plastic IC packaging technology is used, excessive mechanical stress should be avoided when fastening the device with a clamp or a screw-on heat tab. Thermally conductive epoxy or glue, which must be electrically nonconductive, is recommended under typical mounting conditions.

These temperature sensors, as well as any associated circuitry, should be kept insulated and dry to avoid leakage and corrosion. In wet or corrosive environments, any electrically isolated metal or ceramic well can be used to shield the temperature sensors. Condensation at very cold temperatures can cause errors and should be avoided by sealing the device, using electrically nonconductive epoxy paints or dip or any one of the many printed circuit board coatings and varnishes.

THERMAL ENVIRONMENT EFFECTS

The thermal environment in which the TMP35/TMP36/TMP37 sensors are used determines two important characteristics: self-heating effects and thermal response time. Figure 23 illustrates a thermal model of the TMP35/TMP36/TMP37 temperature sensors, which is useful in understanding these characteristics.

Figure 23. Thermal Circuit Model

In the T-3 package, the thermal resistance junction-to-case, θ_{JC} , is 120°C/W . The thermal resistance case-to-ambient, C_A , is the difference between θ_{JA} and θ_{JC} , and is determined by the characteristics of the thermal connection. The power dissipation of the temperature sensor, P_D , is the product of the total voltage across the device and its total supply current, including any current delivered to the load. The rise in die temperature above the ambient temperature of the medium is given by

$$T_J = P_D \times (\theta_{JC} + \theta_{CA}) + T_A$$

Thus, the die temperature rise of a TMP35 SOT-23 package mounted into a socket in still air at 25°C and driven from a 5 V supply is less than 0.04°C .

The transient response of the TMP35/TMP36/TMP37 sensors to a step change in the temperature is determined by the thermal resistances and the thermal capacities of the die, C_{CH} , and the case, C_C . The thermal capacity of C_C varies with the measurement medium because it includes anything in direct contact with the package. In all practical cases, the thermal capacity of C_C is the limiting factor in the thermal response time of the sensor and can be represented by a single-pole RC time constant response. Figure 17 and Figure 19 show the thermal response time of the TMP35/TMP36/TMP37 sensors under various conditions. The thermal time constant of a temperature sensor is defined as the time required for the sensor to reach 63.2% of the final value for a step change in the temperature. For example, the thermal time constant of a TMP35 SOIC package sensor mounted onto a $0.5'' \times 0.3''$ PCB is less than 50 sec in air, whereas in a stirred oil bath, the time constant is less than 3 sec.

BASIC TEMPERATURE SENSOR CONNECTIONS

Figure 24 illustrates the basic circuit configuration for the **TMP35/TMP36/TMP37** temperature sensors. The table in Figure 24 shows the pin assignments of the temperature sensors for the three package types. For the SOT-23, Pin 3 is labeled NC, as are Pin 2, Pin 3, Pin 6, and Pin 7 on the SOIC_N package. It is recommended that no electrical connections be made to these pins. If the shutdown feature is not needed on the SOT-23 or on the SOIC_N package, the **SHUTDOWN** pin should be connected to +V_S.

Figure 24. Basic Temperature Sensor Circuit Configuration

Note the 0.1 µF bypass capacitor on the input. This capacitor should be a ceramic type, have very short leads (surface-mount is preferable), and be located as close as possible in physical proximity to the temperature sensor supply pin. Because these temperature sensors operate on very little supply current and may be exposed to very hostile electrical environments, it is important to minimize the effects of radio frequency interference (RFI) on these devices. The effect of RFI on these temperature sensors specifically and on analog ICs in general is manifested as abnormal dc shifts in the output voltage due to the rectification of the high frequency ambient noise by the IC. When the devices are operated in the presence of high frequency radiated or conducted noise, a large value tantalum capacitor (±2.2 µF) placed across the 0.1 µF ceramic capacitor may offer additional noise immunity.

FAHRENHEIT THERMOMETERS

Although the **TMP35/TMP36/TMP37** temperature sensors are centigrade temperature sensors, a few components can be used to convert the output voltage and transfer characteristics to directly read Fahrenheit temperatures. Figure 25 shows an example of a simple Fahrenheit thermometer using either the **TMP35** or the **TMP37**. Using the **TMP35**, this circuit can be used to sense temperatures from 41°F to 257°F with an output transfer characteristic of 1 mV/°F; using the **TMP37**, this circuit can be used to sense temperatures from 41°F to 212°F with an output transfer characteristic of 2 mV/°F. This particular approach does not lend itself to the **TMP36** because of its inherent 0.5 V output offset. The circuit is constructed with an **AD589**, a 1.23 V voltage reference, and four resistors whose values for each sensor are shown in the table in Figure 25. The scaling of the output resistance levels ensures minimum output loading on the temperature sensors. A generalized expression for the transfer equation of the circuit is given by

$$V_{OUT} = \left(\frac{R1}{R1 + R2} \right) (TMP35) + \left(\frac{R3}{R3 + R4} \right) (AD589)$$

where:

TMP35 is the output voltage of the **TMP35** or the **TMP37** at the measurement temperature, T_M.

AD589 is the output voltage of the reference, that is, 1.23 V.

The output voltage of this circuit is not referenced to the circuit's common ground. If this output voltage were applied directly to the input of an ADC, the ADC common ground should be adjusted accordingly.

SENSOR	TCV _{OUT}	R1 (kΩ)	R2 (kΩ)	R3 (kΩ)	R4 (kΩ)
TMP35	1mV/°F	45.3	10	10	374
TMP37	2mV/°F	45.3	10	10	182

Figure 25. **TMP35/TMP37** Fahrenheit Thermometers

The same circuit principles can be applied to the [TMP36](#), but because of the inherent offset of the [TMP36](#), the circuit uses only two resistors, as shown in Figure 26. In this circuit, the output voltage transfer characteristic is 1 mV/°F but is referenced to the common ground of the circuit; however, there is a 58 mV (58°F) offset in the output voltage. For example, the output voltage of the circuit reads 18 mV if the [TMP36](#) is placed in a -40°F ambient environment and 315 mV at +257°F.

Figure 26. [TMP36](#) Fahrenheit Thermometer Version 1

At the expense of additional circuitry, the offset produced by the circuit in Figure 26 can be avoided by using the circuit in Figure 27. In this circuit, the output of the [TMP36](#) is conditioned by a single-supply, micropower op amp, the [OP193](#). Although the entire circuit operates from a single 3 V supply, the output voltage of the circuit reads the temperature directly, with a transfer characteristic of 1 mV/°F, without offset. This is accomplished through an [ADM660](#), which is a supply voltage inverter. The 3 V supply is inverted and applied to the V- terminal of the [OP193](#). Thus, for a temperature range between -40°F and +257°F, the output of the circuit reads -40 mV to +257 mV. A general expression for the transfer equation of the circuit is given by

$$V_{OUT} = \left(\frac{R6}{R5 + R6} \right) \left(1 + \frac{R4}{R3} \right) (TMP36) - \left(\frac{R4}{R3} \right) \left(\frac{V_S}{2} \right)$$

Figure 27. [TMP36](#) Fahrenheit Thermometer Version 2

AVERAGE AND DIFFERENTIAL TEMPERATURE MEASUREMENT

In many commercial and industrial environments, temperature sensors often measure the average temperature in a building, or the difference in temperature between two locations on a factory floor or in an industrial process. The circuits in Figure 28 and Figure 29 demonstrate an inexpensive approach to average and differential temperature measurement.

In Figure 28, an **OP193** sums the outputs of three temperature sensors to produce an output voltage scaled by 10 mV/°C that represents the average temperature at three locations. The circuit can be extended to include as many temperature sensors as required as long as the transfer equation of the circuit is maintained. In this application, it is recommended that one temperature sensor type be used throughout the circuit; otherwise, the output voltage of the circuit cannot produce an accurate reading of the various ambient conditions.

The circuit in Figure 29 illustrates how a pair of **TMP35/TMP36/TMP37** sensors used with an **OP193** configured as a difference amplifier can read the difference in temperature between two locations. In these applications, it is always possible that one temperature sensor is reading a temperature below that of the other sensor. To accommodate this condition, the output of the **OP193** is offset to a voltage at one-half the supply via **R5** and **R6**. Thus, the output voltage of the circuit is measured relative to this point, as shown in Figure 29. Using the **TMP36**, the output voltage of the circuit is scaled by 10 mV/°C. To minimize the error in the difference between the two measured temperatures, a common, readily available thin-film resistor network is used for **R1** to **R4**.

Figure 28. Configuring Multiple Sensors for Average Temperature Measurements

NOTE:

Figure 29. Configuring Multiple Sensors for Differential Temperature Measurements

MICROPROCESSOR INTERRUPT GENERATOR

These inexpensive temperature sensors can be used with a voltage reference and an analog comparator to configure an interrupt generator for microprocessor applications. With the popularity of fast microprocessors, the need to indicate a microprocessor overtemperature condition has grown tremendously. The circuit in Figure 30 demonstrates one way to generate an interrupt using a **TMP35**, a **CMP402** analog comparator, and a **REF191**, a 2 V precision voltage reference.

The circuit is designed to produce a logic high interrupt signal if the microprocessor temperature exceeds 80°C. This 80°C trip point was arbitrarily chosen (final value set by the microprocessor thermal reference design) and is set using an R3 to R4 voltage divider of the **REF191** output voltage. Because the output of the **TMP35** is scaled by 10 mV/°C, the voltage at the inverting terminal of the **CMP402** is set to 0.8 V.

Because temperature is a slowly moving quantity, the possibility for comparator chatter exists. To avoid this condition, hysteresis is used around the comparator. In this application, a hysteresis of 5°C about the trip point was arbitrarily chosen; the ultimate value for hysteresis should be determined by the end application. The output logic voltage swing of the comparator with R1 and R2 determines the amount of comparator hysteresis. Using a 3.3 V supply, the output logic voltage swing of the **CMP402** is 2.6 V; therefore, for a hysteresis of 5°C (50 mV at 10 mV/°C), R1 is set to 20 kΩ, and R2 is set to 1 MΩ. An expression for the hysteresis of this circuit is given by

$$V_{HYS} = \left(\frac{R1}{R2} \right) (V_{LOGIC SWING, CMP402})$$

Because this circuit is probably used in close proximity to high speed digital circuits, R1 is split into equal values and a 1000 pF capacitor is used to form a low-pass filter on the output of the **TMP35**. Furthermore, to prevent high frequency noise from contaminating the comparator trip point, a 0.1 μF capacitor is used across R4.

Figure 30. Microprocessor Overtemperature Interrupt Generator

00337-028

THERMOCOUPLE SIGNAL CONDITIONING WITH COLD-JUNCTION COMPENSATION

The circuit in Figure 31 conditions the output of a Type K thermocouple, while providing cold-junction compensation for temperatures between 0°C and 250°C. The circuit operates from a single 3.3 V to 5.5 V supply and is designed to produce an output voltage transfer characteristic of 10 mV/°C.

A Type K thermocouple exhibits a Seebeck coefficient of approximately 41 $\mu\text{V}/^\circ\text{C}$; therefore, at the cold junction, the TMP35, with a temperature coefficient of 10 mV/°C, is used with R1 and R2 to introduce an opposing cold-junction temperature coefficient of $-41 \mu\text{V}/^\circ\text{C}$. This prevents the isothermal, cold-junction connection between the PCB tracks of the circuit

and the wires of the thermocouple from introducing an error in the measured temperature. This compensation works extremely well for circuit ambient temperatures in the range of 20°C to 50°C. Over a 250°C measurement temperature range, the thermocouple produces an output voltage change of 10.151 mV. Because the required output full-scale voltage of the circuit is 2.5 V, the gain of the circuit is set to 246.3. Choosing R4 equal to 4.99 k Ω sets R5 equal to 1.22 M Ω . Because the closest 1% value for R5 is 1.21 M Ω , a 50 k Ω potentiometer is used with R5 for fine trim of the full-scale output voltage. Although the OP193 is a superior single-supply, micropower operational amplifier, its output stage is not rail-to-rail; therefore, the 0°C output voltage level is 0.1 V. If this circuit is digitized by a single-supply ADC, the ADC common should be adjusted to 0.1 V accordingly.

Figure 31. Single-Supply, Type K Thermocouple Signal Conditioning Circuit with Cold-Junction Compensation

USING TMP35/TMP36/TMP37 SENSORS IN REMOTE LOCATIONS

In many industrial environments, sensors are required to operate in the presence of high ambient noise. These noise sources take many forms, for example, SCR transients, relays, radio transmitters, arc welders, and ac motors. They can also be used at considerable distances from the signal conditioning circuitry. These high noise environments are typically in the form of electric fields, so the voltage output of the temperature sensor can be susceptible to contamination from these noise sources.

Figure 32 illustrates a way to convert the output voltage of a TMP35/TMP36/TMP37 sensor into a current to be transmitted down a long twisted pair shielded cable to a ground referenced receiver. The temperature sensors are not capable of high output current operation; thus, a standard PNP transistor is used to boost the output current drive of the circuit. As shown in the table in Figure 32, the values of R2 and R3 were chosen to produce an arbitrary full-scale output current of 2 mA. Lower values for the full-scale current are not recommended. The minimum-scale output current produced by the circuit could be contaminated by ambient magnetic fields operating in the near vicinity of the circuit/cable pair. Because the circuit uses an external transistor, the minimum recommended operating voltage for this circuit is 5 V. To minimize the effects of EMI (or RFI), both the circuit and the temperature sensor supply pins are bypassed with good quality ceramic capacitors.

Figure 32. Remote, 2-Wire Boosted Output Current Temperature Sensor

TEMPERATURE TO 4–20 mA LOOP TRANSMITTER

In many process control applications, 2-wire transmitters are used to convey analog signals through noisy ambient environments. These current transmitters use a zero-scale signal current of 4 mA, which can be used to power the signal conditioning circuitry of the transmitter. The full-scale output signal in these transmitters is 20 mA.

Figure 33 illustrates a circuit that transmits temperature information in this fashion. Using a TMP35/TMP36/TMP37 as the temperature sensor, the output current is linearly proportional to the temperature of the medium. The entire circuit operates from the 3 V output of the REF193. The REF193 requires no external trimming because of its tight initial output voltage tolerance and the low supply current of the TMP35/TMP36/TMP37, the OP193, and the REF193. The entire circuit consumes less than 3 mA from a total budget of 4 mA. The OP193 regulates the output current to satisfy the current summation at the noninverting node of the OP193. A generalized expression for the KCL equation at Pin 3 of the OP193 is given by

$$I_{OUT} = \left(\frac{1}{R7} \right) \times \left(\frac{TMP3x \times R3}{R1} + \frac{V_{REF} \times R3}{R2} \right)$$

For each temperature sensor, Table 5 provides the values for the components P1, P2, and R1 to R4.

Table 5. Circuit Element Values for Loop Transmitter

Sensor	R1	P1	R2	P2	R3	R4
TMP35	97.6 kΩ	5 kΩ	1.58 MΩ	100 kΩ	140 kΩ	56.2 kΩ
TMP36	97.6 kΩ	5 kΩ	931 kΩ	50 kΩ	97.6 kΩ	47 kΩ
TMP37	97.6 kΩ	5 kΩ	10.5 kΩ	500 Ω	84.5 kΩ	8.45 kΩ

The 4 mA offset trim is provided by P2, and P1 provides the full-scale gain trim of the circuit at 20 mA. These two trims do not interact because the noninverting input of the OP193 is held at a virtual ground. The zero-scale and full-scale output currents of the circuit are adjusted according to the operating temperature range of each temperature sensor. The Schottky diode, D1, is required in this circuit to prevent loop supply power-on transients from pulling the noninverting input of the OP193 more than 300 mV below its inverting input. Without this diode, such transients can cause phase reversal of the operational amplifier and possible latch-up of the transmitter. The loop supply voltage compliance of the circuit is limited by the maximum applied input voltage to the REF193; it is from 9 V to 18 V.

TEMPERATURE-TO-FREQUENCY CONVERTER

Another common method of transmitting analog information from a remote location is to convert a voltage to an equivalent value in the frequency domain. This is readily done with any of the low cost, monolithic voltage-to-frequency converters (VFCs) available. These VFCs feature a robust, open-collector output transistor for easy interfacing to digital circuitry. The digital signal produced by the VFC is less susceptible to contamination from external noise sources and line voltage drops because the only important information is the frequency of the digital signal. When the conversions between temperature and frequency are done accurately, the temperature data from the sensors can be reliably transmitted.

The circuit in Figure 34 illustrates a method by which the outputs of these temperature sensors can be converted to a frequency using the AD654. The output signal of the AD654 is a square wave that is proportional to the dc input voltage across Pin 4 and Pin 3. The transfer equation of the circuit is given by

$$f_{OUT} = \left(\frac{V_{TPM} - V_{OFFSET}}{10 \times (R_T \times C_T)} \right)$$

Figure 34. Temperature-to-Frequency Converter

An offset trim network ($f_{OUT\ OFFSET}$) is included with this circuit to set f_{OUT} to 0 Hz when the minimum output voltage of the temperature sensor is reached. Potentiometer P1 is required to calibrate the absolute accuracy of the AD654. The table in Figure 34 illustrates the circuit element values for each of the three sensors. The nominal offset voltage required for 0 Hz output from the TMP35 is 50 mV; for the TMP36 and TMP37, the offset voltage required is 100 mV. For the circuit values shown, the output frequency transfer characteristic of the circuit was set at 50 Hz/°C in all cases. At the receiving end, a frequency-to-voltage converter (FVC) can be used to convert the frequency back to a dc voltage for further processing. One such FVC is the AD650.

For complete information about the AD650 and the AD654, consult the individual data sheets for those devices.

DRIVING LONG CABLES OR HEAVY CAPACITIVE LOADS

Although the TMP35/TMP36/TMP37 temperature sensors can drive capacitive loads up to 10,000 pF without oscillation, output voltage transient response times can be improved by using a small resistor in series with the output of the temperature sensor, as shown in Figure 35. As an added benefit, this resistor forms a low-pass filter with the cable capacitance, which helps to reduce bandwidth noise. Because the temperature sensor is likely to be used in environments where the ambient noise level can be very high, this resistor helps to prevent rectification by the devices of the high frequency noise. The combination of this resistor and the supply bypass capacitor offers the best protection.

COMMENTARY ON LONG-TERM STABILITY

The concept of long-term stability has been used for many years to describe the amount of parameter shift that occurs during the lifetime of an IC. This is a concept that has been typically applied to both voltage references and monolithic temperature sensors. Unfortunately, integrated circuits cannot be evaluated at room temperature (25°C) for 10 years or more to determine this shift. As a result, manufacturers very typically perform accelerated lifetime testing of integrated circuits by operating ICs at elevated temperatures (between 125°C and 150°C) over a shorter period of time (typically, between 500 and 1000 hours).

As a result of this operation, the lifetime of an integrated circuit is significantly accelerated due to the increase in rates of reaction within the semiconductor material.

Figure 1: Dimensions of the test fixture. The figure shows two views of a test fixture: a top view and a side view. The top view shows a rectangular board with dimensions 5.00 (0.1968) and 4.80 (0.1890) in inches. It has four pins on the top edge, four on the bottom edge, and two on the left edge. The bottom edge pins are labeled 1, 4, 5, and 8. The distance from the top edge to the bottom edge pins is 4.00 (0.1574) inches, and the distance from the bottom edge pins to the bottom edge is 3.80 (0.1497) inches. The distance from the left edge to the right edge pins is 6.20 (0.2441) inches, and the distance from the right edge pins to the right edge is 5.80 (0.2284) inches. The distance between the bottom edge pins is 1.27 (0.0500) inches, labeled BSC. The side view shows the board thickness as 0.25 (0.0098) inches, with a coplanarity of 0.10 (0.0040) inches. The board is seated on a seating plane. The distance from the seating plane to the top edge is 0.10 (0.0040) inches. The distance from the seating plane to the bottom edge pins is 0.51 (0.0201) inches, and the distance from the bottom edge pins to the bottom edge is 0.31 (0.0122) inches. The distance from the seating plane to the right edge pins is 1.75 (0.0688) inches, and the distance from the right edge pins to the right edge is 1.35 (0.0532) inches. The side view also shows a 45-degree angle and a 0-degree angle. The distance from the seating plane to the right edge pins is 0.25 (0.0098) inches, and the distance from the right edge pins to the right edge is 0.17 (0.0067) inches. The distance from the seating plane to the bottom edge pins is 0.25 (0.0098) inches, and the distance from the bottom edge pins to the bottom edge is 0.40 (0.0157) inches.

TMP37FT9Z	±2.0	5°C to 100°C	3-Pin Plastic Header-Style Package (TO-92)	T-3-1	
TMP37GRTZ-REEL7	±3.0	5°C to 100°C	5-Lead Small Outline Transistor Package (SOT-23)	RJ-5	#T12

¹ Z = RoHS Compliant Part.

² W = Qualified for Automotive Applications.

AUTOMOTIVE PRODUCTS

The ADW75001Z-0REEL7 model is available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that this automotive model may have specifications that differ from the commercial models; therefore, designers should review the Specifications section of this data sheet carefully. Only automotive grade products shown are available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for these models.
