5. Handling Precautions

Any semiconductor devices have inherently a certain rate of failure. The possibility of failure is greatly affected by the conditions in which they are used (circuit conditions, environmental conditions, etc.). This page describes precautions that must be observed to minimize the chance of failure and to obtain higher reliability from your Cypress semiconductor devices.

5.1 Precautions for Product Design

This section describes precautions when designing electronic equipment using semiconductor devices.

■Absolute Maximum Ratings

Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of certain established limits, called absolute maximum ratings. Do not exceed these ratings.

■Recommended Operating Conditions

Recommended operating conditions are normal operating ranges for the semiconductor device. All the device's electrical characteristics are warranted when operated within these ranges.

Always use semiconductor devices within the recommended operating conditions. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their sales representative beforehand.

■Processing and Protection of Pins

These precautions must be followed when handling the pins which connect semiconductor devices to power supply and input/output functions.

1. Preventing Over-Voltage and Over-Current Conditions

   Exposure to voltage or current levels in excess of maximum ratings at any pin is likely to cause deterioration within the device, and in extreme cases leads to permanent damage of the device. Try to prevent such overvoltage or over-current conditions at the design stage.

2. Protection of Output Pins

   Shorting of output pins to supply pins or other output pins, or connection to large capacitance can cause large current flows. Such conditions if present for extended periods of time can damage the device.
   Therefore, avoid this type of connection.

3. Handling of Unused Input Pins

Unconnected input pins with very high impedance levels can adversely affect stability of operation. Such pins should be connected through an appropriate resistance to a power supply pin or ground pin.

■Latch-up

Semiconductor devices are constructed by the formation of P-type and N-type areas on a substrate. When subjected to abnormally high voltages, internal parasitic PNPN junctions (called thyristor structures) may be formed, causing large current levels in excess of several hundred mA to flow continuously at the power supply pin. This condition is called latch-up.

CAUTION: The occurrence of latch-up not only causes loss of reliability in the semiconductor device, but can cause injury or damage from high heat, smoke or flame. To prevent this from happening, do the following:

1. Be sure that voltages applied to pins do not exceed the absolute maximum ratings. This should include attention to abnormal noise, surge levels, etc.
2. Be sure that abnormal current flows do not occur during the power-on sequence.

■Observance of Safety Regulations and Standards

Most countries in the world have established standards and regulations regarding safety, protection from electromagnetic interference, etc. Customers are requested to observe applicable regulations and standards in the design of products.

■Fail-Safe Design

Any semiconductor devices have inherently a certain rate of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

■Precautions Related to Usage of Devices
Cypress semiconductor devices are intended for use in standard applications (computers, office automation and other office equipment, industrial, communications, and measurement equipment, personal or household devices, etc.).

CAUTION: Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

5.2 Precautions for Package Mounting

Package mounting may be either lead insertion type or surface mount type. In either case, for heat resistance during soldering, you should only mount under Cypress's recommended conditions. For detailed information about mount conditions, contact your sales representative.

■Lead Insertion Type
Mounting of lead insertion type packages onto printed circuit boards may be done by two methods: direct soldering on the board, or mounting by using a socket.

Direct mounting onto boards normally involves processes for inserting leads into through-holes on the board and using the flow soldering (wave soldering) method of applying liquid solder. In this case, the soldering process usually causes leads to be subjected to thermal stress in excess of the absolute ratings for storage temperature. Mounting processes should conform to Cypress recommended mounting conditions.

If socket mounting is used, differences in surface treatment of the socket contacts and IC lead surfaces can lead to contact deterioration after long periods. For this reason it is recommended that the surface treatment of socket contacts and IC leads be verified before mounting.

■Surface Mount Type
Surface mount packaging has longer and thinner leads than lead-insertion packaging, and therefore leads are more easily deformed or bent. The use of packages with higher pin counts and narrower pin pitch results in increased susceptibility to open connections caused by deformed pins, or shorting due to solder bridges.

You must use appropriate mounting techniques. Cypress recommends the solder reflow method, and has established a ranking of mounting conditions for each product. Users are advised to mount packages in accordance with Cypress ranking of recommended conditions.

■Lead-Free Packaging
CAUTION: When ball grid array (BGA) packages with Sn-Ag-Cu balls are mounted using Sn-Pb eutectic soldering, junction strength may be reduced under some conditions of use.

■Storage of Semiconductor Devices
Because plastic chip packages are formed from plastic resins, exposure to natural environmental conditions will cause absorption of moisture. During mounting, the application of heat to a package that has absorbed moisture can cause surfaces to peel, reducing moisture resistance and causing packages to crack. To prevent, do the following:

1. Avoid exposure to rapid temperature changes, which cause moisture to condense inside the product. Store products in locations where temperature changes are slight.
2. Use dry boxes for product storage. Products should be stored below 70% relative humidity, and at temperatures between 5°C and 30°C.
   When you open Dry Package that recommends humidity 40% to 70% relative humidity.
3. When necessary, Cypress. packages semiconductor devices in highly moisture-resistant aluminum laminate bags, with a silica gel desiccant. Devices should be sealed in their aluminum laminate bags for storage.
4. Avoid storing packages where they are exposed to corrosive gases or high levels of dust.

■Baking
Packages that have absorbed moisture may be de-moisturized by baking (heat drying). Follow the Cypress recommended conditions for baking.

Condition: 125°C/24 h

■Static Electricity

Because semiconductor devices are particularly susceptible to damage by static electricity, you must take the following precautions:

1. Maintain relative humidity in the working environment between 40% and 70%. Use of an apparatus for ion generation may be needed to remove electricity.
2. Electrically ground all conveyors, solder vessels, soldering irons and peripheral equipment.
3. Eliminate static body electricity by the use of rings or bracelets connected to ground through high resistance (on the level of 1 MΩ).
   Wearing of conductive clothing and shoes, use of conductive floor mats and other measures to minimize shock loads is recommended.
4. Ground all fixtures and instruments, or protect with anti-static measures.
5. Avoid the use of styrofoam or other highly static-prone materials for storage of completed board assemblies.

5.3 Precautions for Use Environment

Reliability of semiconductor devices depends on ambient temperature and other conditions as described above.

For reliable performance, do the following:

1. Humidity

   Prolonged use in high humidity can lead to leakage in devices as well as printed circuit boards. If high humidity levels are anticipated, consider anti-humidity processing.
2. Discharge of Static Electricity

   When high-voltage charges exist close to semiconductor devices, discharges can cause abnormal operation. In such cases, use anti-static measures or processing to prevent discharges.
3. Corrosive Gases, Dust, or Oil

   Exposure to corrosive gases or contact with dust or oil may lead to chemical reactions that will adversely affect the device. If you use devices in such conditions, consider ways to prevent such exposure or to protect the devices.
4. Radiation, Including Cosmic Radiation

   Most devices are not designed for environments involving exposure to radiation or cosmic radiation. Users should provide shielding as appropriate.
5. Smoke, Flame

CAUTION: Plastic molded devices are flammable, and therefore should not be used near combustible substances. If devices begin to smoke or burn, there is danger of the release of toxic gases.

Customers considering the use of Cypress products in other special environmental conditions should consult with sales representatives.

6. Handling Devices

This section explains the latch-up prevention and treatment of a pin.

■For latch-up prevention
If a voltage higher than VCC or a voltage lower than VSS is applied to an I/O pin, or if a voltage exceeding the ratings is applied between VCC pin and VSS pin, a latch-up may occur in CMOS IC. If the latch-up occurs, the power supply current increases excessively and device elements may be damaged by heat. Take care to prevent any voltage from exceeding the maximum ratings in device application.

Also, the analog power supply (AVCC5, AVRH5), the NTSC power supply (AVCC3, AVR3), analog input and power supply to high-current output buffer pins must not be exceed the digital power supply (VCC5 or VCC3) when the power supply to the analog system and high-current output buffer pins is turned on or off.

In the correct power-on sequence of the microcontroller, turn on the digital power supply (VCC5), analog power supplies (AVCC5, AVRH5), and the power supply of high-current output buffer pins (DVCC) simultaneously. Or, turn on the digital power supply (VCC5), and then turn on analog power supplies (AVCC5, AVRH5) and the power supply of high-current output buffer pins (DVCC).

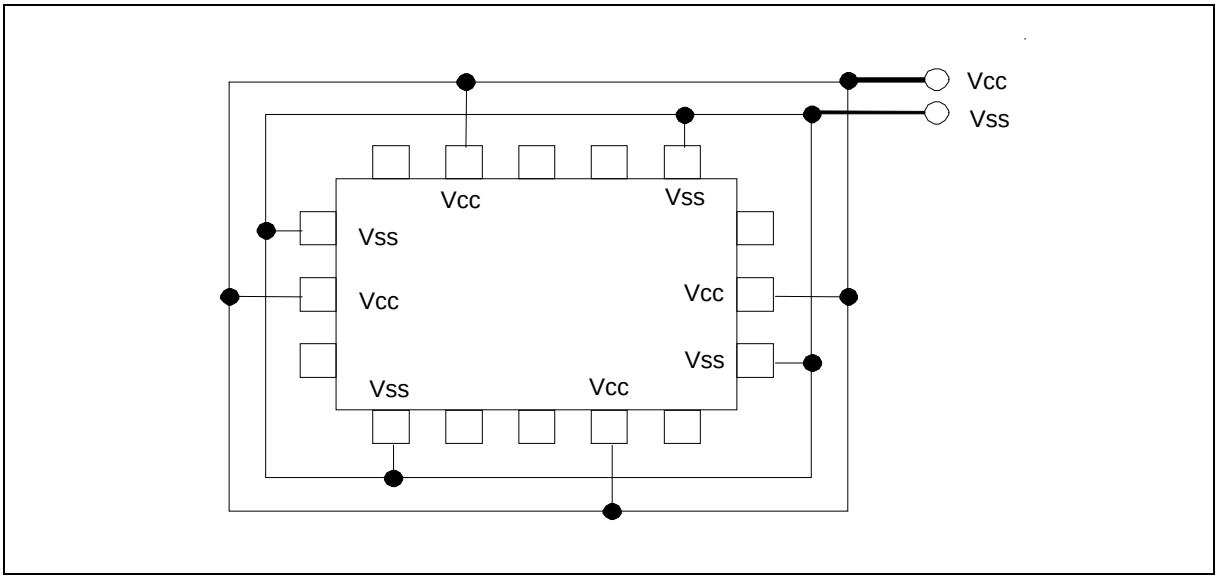
In the correct power-on sequence of GDC, similarly turn on the digital power supply (VCC3) and the NTSC analog power supply (AVCC3) simultaneously. Or, turn on the digital power supply (VCC3), and then turn on the NTSC analog power supply (AVCC3).

■Treatment of unused pins
If unused input pins are left open, they may cause a permanent damage to the device due to malfunction or latch-up. Connect a 2kΩ resistor to each of unused pins for pull-up or pull-down processing.

Also, if I/O pins are not used, they must be set to the output state for opening or they must be set to the input state and treated in the same way as for the input pins.

■Power supply pins
The device is designed to ensure that if the device contains multiple VCC pin or VSS pin, the pins that should be at the same potential are interconnected to prevent latch-up or other malfunctions. Further, connect these pins to an external power supply or ground to reduce unwanted radiation, prevent strobe signals from malfunctioning due to a raised ground level, and fulfill the total output current standard, etc. As shown in Figure 1, all Vss power supply pins must be treated in the similar way. If multiple Vcc or Vss systems are connected, the device cannot operate correctly even within the guaranteed operating range.

Figure 1. Power Supply Input Pins



The power supply pins should be connected to VCC pin and VSS pin of this device at the low impedance from the power supply source.

In the area close to this device, a ceramic capacitor having the capacitance larger than the capacitor of C pin is recommended to use as a bypass capacitor between the VCC pin and the VSS pin.

As for BGA package product, the solder balls of VSS and VCC are placed in the most internal circumference of solder-ball-placement. In order to connect bypass capacitor close to these balls, the capacitors had better be implemented on the back side of a system board surface on which BGA package is implemented.

■Crystal oscillation circuit
An external noise to the X0 pin or X1 pin may cause a device malfunction. The printed circuit board must be designed to lay out the X0 pin and the X1 pin, crystal oscillator (or ceramic resonator), and the bypass capacitor to be grounded to the close position to the device.

The printed circuit board artwork is recommended to surround the X0 pin and X1 pin by ground circuits.

■Mode pins (MD2, MD1, MD0)
Connect the MD2, MD1and MD0 mode pin to the VCC pin or VSS pin directly. To prevent an erroneous selection of test mode caused by the noise, reduce the pattern length between each mode pin and the VCC pin or VSS pin on the printed circuit board. Also, use the low-impedance pin connection.

■During power-on
To prevent a malfunction of the voltage step-down circuit built in the device, set the voltage rising time to have 50µs or longer (between 0.2V and 2.7V) during power-on.

■Notes during PLL clock operation
When the PLL clock is selected and if the oscillator is disconnected or if the input is stopped, this clock may continue to operate at the free running frequency of the self-oscillator circuit built in the PLL clock. This operation is not guaranteed.

■Treatment of A/D converter power supply pins
Connect the pins to have AVCC5=AVRH5=VCC5 and AVSS5/AVRL5=VSS even if the A/D converter is not used.

Also, similarly connect the pins of NTSC A/D converter power supply to have AVCC3=VCC3 and AVSS3=VSS. At this time, open VIN/REFOUT.

■Notes on using external clock
An external clock is not supported. None of the external direct clock input can be used for both main clock and sub clock.

■Power-on sequence of A/D converter analog inputs
Be sure to turn on the digital power supply (Vcc5) first, and then turn on the A/D converter power supplies (AVcc5, AVRH5, AVRL5) and analog inputs (AN0 to AN31). Also, turn off the A/D converter power supplies and analog inputs first, and then turn off the digital power supply (Vcc5). When the AVRH5 pin voltage is turned on or off, it must not exceed AVCC5. Even if a common analog input pin is used as an input port, its input voltage must not exceed AVcc5. (However, the analog power supply and digital power supply can be turned on or off simultaneously.)

Be sure to similarly turn on the digital power supply (VCC3) first, and then turn on the A/D converter power supply (AVCC3) for NTSC and NTSC inputs (VIN, AVR). Also, turn off the A/D converter power supplies and analog inputs first, and then turn off the digital power supply (VCC3).

■Treatment of power supplies for high current output buffer pins (DVcc, DVss)
Be sure to turn on the digital power supply (Vcc) first, and then turn on the power supplies for high current output buffer pins (DVcc, DVss). Also, turn off the power supplies for high current output buffer pins first, and then turn off the digital power supply (Vcc).

Even if the high current output buffer pins are used as general-purpose ports, the power supplies of high current output buffer pins (DVcc, DVss) must be powered. (The power supplies of high current output buffer pins and the digital power supplies can be turned on or off simultaneously.)

■Treatment of C pin
This device contains a voltage step-down circuit. A capacitor must always be connected to the C pin to assure the internal stabilization of the device. For the standard values, see the "Recommended Operating Conditions" of the latest data sheet.

■Function switching of a multiplexed port
To switch between the port function and the multiplexed pin function, use the PFR (port function register).

■Low-power consumption mode
To transit to the sleep mode, watch mode, stop mode, watch mode(power-off) or stop mode(power-off), follow the procedure explained in the "Activating the sleep mode, watch mode, or stop mode" or the "Activating the watch mode (power-off) or stop mode(power-off)" of " POWER CONSUMPTION CONTROL".

Power supply for GDC can be turned off separately from the microcontroller.

Take the following notes when using a monitor debugger.

- Do not set a break point for the low-power consumption transition program.
- Do not execute an operation step for the low-power consumption transition program.

■Precautions when writing to registers including the status flag
When writing data in the register that has a status flag (especially, an interrupt request flag) to control function, taking care not to clear its status flag erroneously must be followed.

The program must be written not to clear the flag to the status bit, and then to set the control bits to have the desired value.

Especially, if multiple control bits are used, the bit instruction cannot be used. (The bit instruction can access to a single bit only.) By the Byte, Half-word, or Word access, data is written to the control bits and status flag simultaneously. During this time, take care not to clear other bits (in this case, the bits of status flag) erroneously.

Note:

These points can be ignored because the bit instructions to a register which supports RMW are already taken the points into consideration. Care must be taken when the bit instruction is used to a register which does not support RMW.

[*1]: These parameters are based on the condition that V_{SS}=AV_{SS}=DV_{SS}=0.0V

[*2]: Caution must be taken that $AV_{CC}5$ and DV_{CC} do not exceed $V_{CC}5$.Similarly,$AV_{CC}3$ must not exceed $V_{CC}3$.

[*3]: The maximum output current is defined as the value of the peak current flowing through any one of the corresponding pins.

[*4]: The average output current is defined as the value of the average current flowing through any one of the corresponding pins for a 10 ms period. The average value is the operation current × the operation ratio.

[*5]: The total output current is defined as the maximum current value flowing through all of corresponding pins.

[*6]: Outputs other than P60-P87 and 3V pin.

*7: Output of P60-P87 pins.

*8: Output of 3V pin.

*9: Corresponding pins: all general-purpose ports except P90/ADTG.(Except for the dedicated analog port)

- Use within recommended operating conditions.
- Use at DC voltage (current).
- The + B signal should always be applied by connecting a limiting resistor between the + B signal and the microcontroller.
- The value of the limiting resistor should be set so that the current input to the microcontroller pin does not exceed rated values at any time regardless of instantaneously or constantly when the + B signal is input.
- Note that when the microcontroller drive current is low, such as in the low power consumption modes, the + B input potential can increase the potential at the VCC pin via a protective diode, possibly affecting other devices.
- Note that if the + B signal is input when the microcontroller is off (not fixed at 0 V), since the power is supplied through the pin, the microcontroller may operate incompletely.
- Note that if the +B signal is input at power-on, since the power is supplied through the pin, the power-on reset may not function in the power supply voltage.
- Do not leave + B input pins open.

WARNING

Semiconductor devices may be permanently damaged by application of stress (including, without limitation, voltage, current or temperature) in excess of absolute maximum ratings. Do not exceed any of these ratings.

*1: The power supply current value when the external clock is supplied from the X1 pin. Note that the power supply current value when using the external clock is different from that using the oscillator.

*2: If PWM1P0/PWM1M0/PWM2P0/PWM2M0 of ch.0 is turned on simultaneously, the maximum deviation of V_{OH3} / V_{OL3} for each pin is defined. Same for other channels.

*3: This product contains both program Flash and WorkFlash. This parameter is defined when only one of them is in the write/erase state.

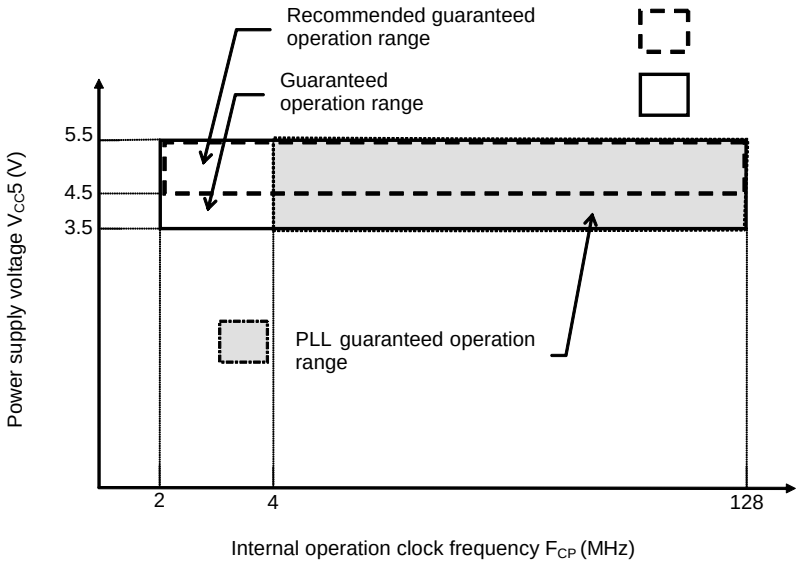
Guaranteed Operation Range (5V Operating microcontroller Section)

Internal operation clock frequency vs. Power supply voltage

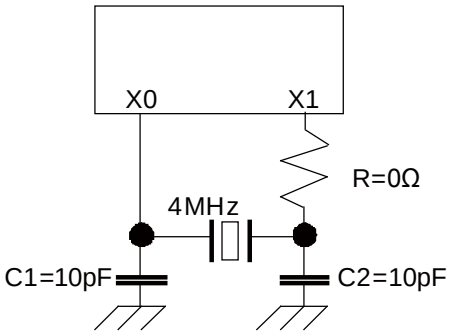


Note: The CPU will be reset at the power supply voltage 4V±0.3V or less.

Oscillation Clock Frequency vs. Internal Operation Clock Frequency

		Internal Operation Clock Frequency							
		Main Clock	PLL Clock						
			Multiplied by 1	Multiplied by 2	Multiplied by 3	Multiplied by 4	...	Multiplied by 20	Multiplied by 32
Oscillation clock frequency	4MHz	2MHz	4MHz	8MHz	12MHz	16MHz	...	80MHz	128MHz

• Example of Oscillation Circuit

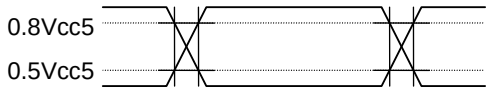


Note: As to the product with its clock supervisor's initial value is "ON", when the oscillator is unable to start within 20ms from the stop state the clock supervisor will detect the oscillation stop. As a result, the CPU moves to the fail safe operation.
Design your printed circuit board so that the oscillator can start oscillation within 20ms.

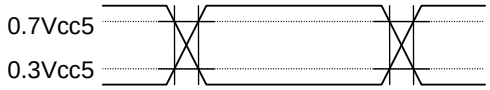
AC characteristics are specified by the following measurement reference voltage values.

• Input Signal Waveform

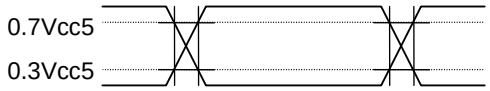
Hysteresis Input Pin (Automotive)



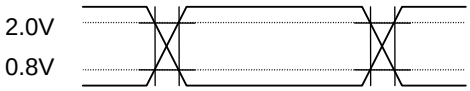
Hysteresis Input Pin (CMOS Normal)



Hysteresis Input Pin (CMOS Hysteresis)



TTL Input Pin



• Output Signal Waveform

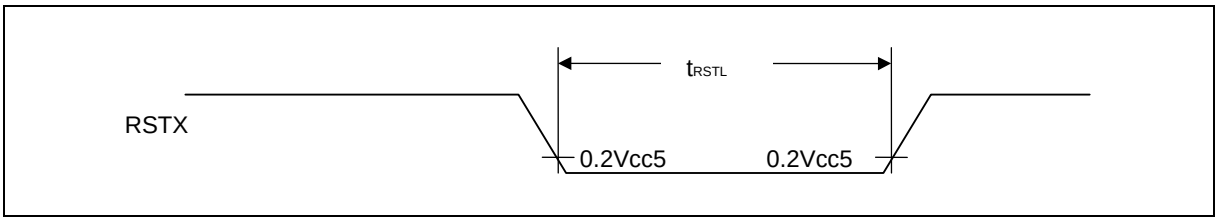
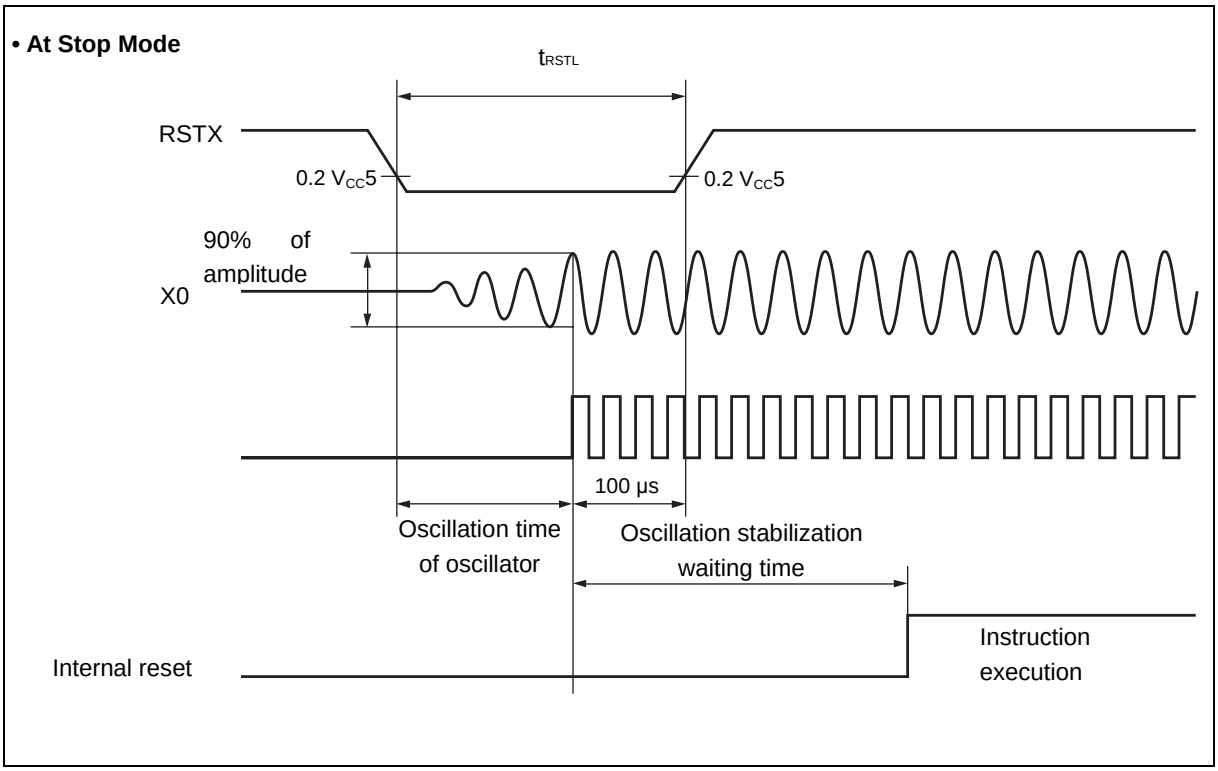
11.4.1.2 Reset Input

(T_A: Recommended operating conditions, $V_{CC}5$=5.0V ± 10%, V_{SS}=AV_{SS}=0.0V)

Parameter	Symbol	Pin Name	Conditions	Value		Unit	Remarks
				Min	Max		
Reset input time	t_{RSTL}	RSTX	–	10	–	µs	When normal operation
				Oscillation time of oscillator* + 100µs	–	ms	At Stop mode
				100µs	–	µs	At RTC mode
Width for reset input removal				1µs	–	µs	

*:The oscillation time of the oscillator is the time it takes for the amplitude of the oscillations to reach 90%. For crystal oscillators, this time is between several ms and several tens of ms, for ceramic oscillators the time is between several hundred µs and several ms, and for an external clock, the time is 0 ms.





11.4.1.3 Power-on Conditions

(T_A: Recommended operating conditions, V_{SS}=0.0V)

Parameter	Symbol	Pin Name	Conditions	Value			Unit	Remarks
				Min	Typ	Max		
Level detection voltage	–	$V_{CC}5$	–	2.1	2.3	2.5	V	When turning on power for microcontroller
Level detection hysteresis width	–	$V_{CC}5$	–	–	–	125	mV	During voltage drop

Specification for voltage slope detection	–	$V_{CC}5$	$V_{CC}5$ = at level detection release level time	–	–	4	mV/µs	*2
Power off time	t_{OFF}	$V_{CC}5$	–	50	–	–	ms	*3

*1: If the fluctuation of the power supply is faster than the low voltage detection time, there is the possibility to generate or release after the power supply voltage has exceeded the detection voltage range.

*2: When setting the power supply fluctuation to this specification or less, it is possible to suppress the voltage slope detection. This is the specification when the power supply fluctuation is stable.

*3: This time is to start the voltage slope detection at next power on after power down and internal charge loss.

*3: A high-speed mode I²C bus device can be used on a standard mode I²C bus system as long as the device satisfies the requirement of "t_{SUDAT} ≥ 250 ns".

*4: t_{CPP} is the peripheral clock cycle time. Adjust the peripheral clock frequency to 8MHz or more when use I²C.

■AC Timing Parameters

This section describes parameters used for AC timing specifications. Select whether you use the DCLKO reverse edge mode, depending on the use/non-use of delay mode.

When the delay mode is not used:
Use the DCLKO reverse edge mode when the external display device (TFT) receives the signal at the rising edge of DCLKO.
Use the DCLKO standard mode when the external display device (TFT) receives the signal at the falling edge of DCLKO.

When the delay mode is used:
Use the DCLKO standard mode when the external display device (TFT) receives the signal at the rising edge of DCLKO.
Use the DCLKO reverse edge mode when the external display device (TFT) receives the signal at the falling edge of DCLKO.

Note: Clock duty ratio when the clock frequency division ratio is even or odd

AC specifications use the half-cycle of the display output clock DCLKO as a parameter. In AC specifications, the first half-cycle is indicated as t_{dcyc_f}, and the second half-cycle is indicated as t_{dcyc_l}.

Note that clock duty ratio will not be 50%:50% when the clock frequency division ratio (specified in SC field of DCM1 register) is odd. If the clock frequency division ratio is odd, the first half-cycle t_{dcyc_f} becomes different from the second half-cycle t_{dcyc_l}.

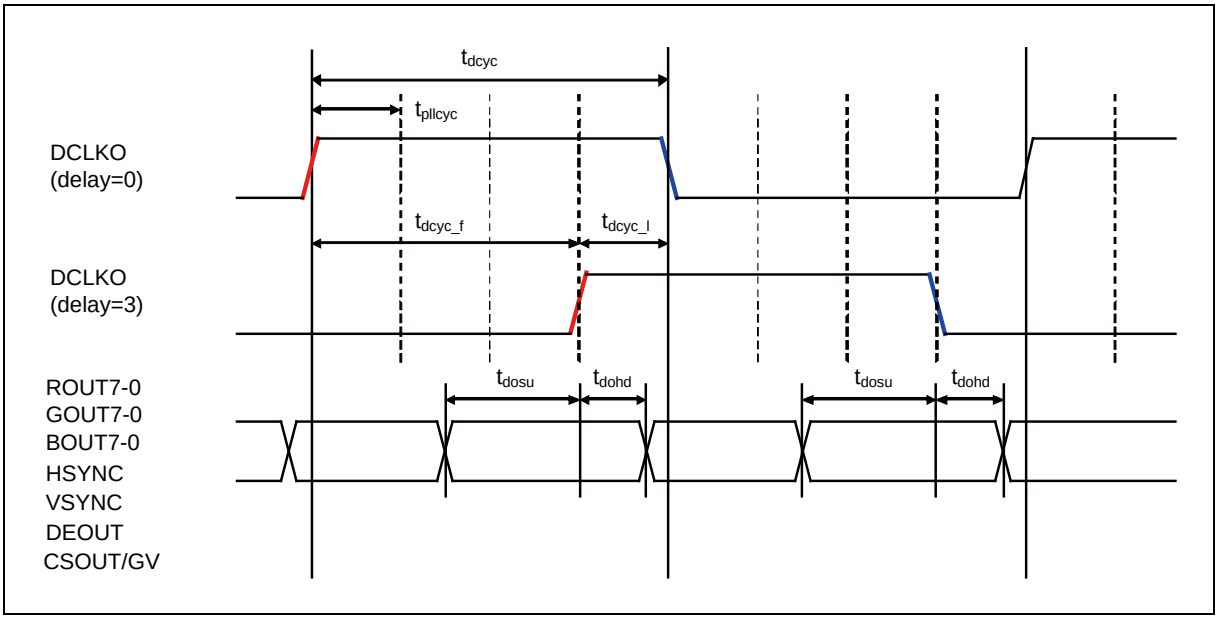
(Example: When frequency division ratio = 4) Although there are two sampling locations in both edge mode; one at the rising edge and the other at the falling edge, the values of setup/hold definition are same.

Figure 7. Built-in PLL Both Edge and Delay Mode Setup/Hold Definition



Setup/Hold Definition in Delay Mode

The delay mode is a mode realized with DCLKO delay function, and it can provide delay to DCLKO signal output itself. This can be used when both the following conditions are satisfied.

- The internal PLL is used to generate DCLKO (CKS field of DCM register = 0)
- The frequency division ratio to the internal PLL of DCLKO is 2 or more (SC field of DCM register > 0)

The delay value is set as the unit for internal PLL clock by DCKD field of DCM3 register. The meanings of DCKD setting value are shown below.

When the internal PLL frequency division ratio = 2

DCKD	Delay
000000	No additional delay
000100	+1 PLL clock

When the internal PLL frequency division ratio > 2

DCKD	Delay
000000	No additional delay
000010	+2 PLL clock
000100	+3 PLL clock
000110	+4 PLL clock
:	:
111110	+17 PLL clock

In delay mode, t_{dcyc_f} and t_{dcyc_l} are defined by the delay value above (e.g. "2" of "+2 PLL clock") as shown below.

t_{dcyc_f} = Delay value × t_{pllcyc}

$t_{dcyc\_l} = t_{dcyc} - t_{dcyc\_f}$

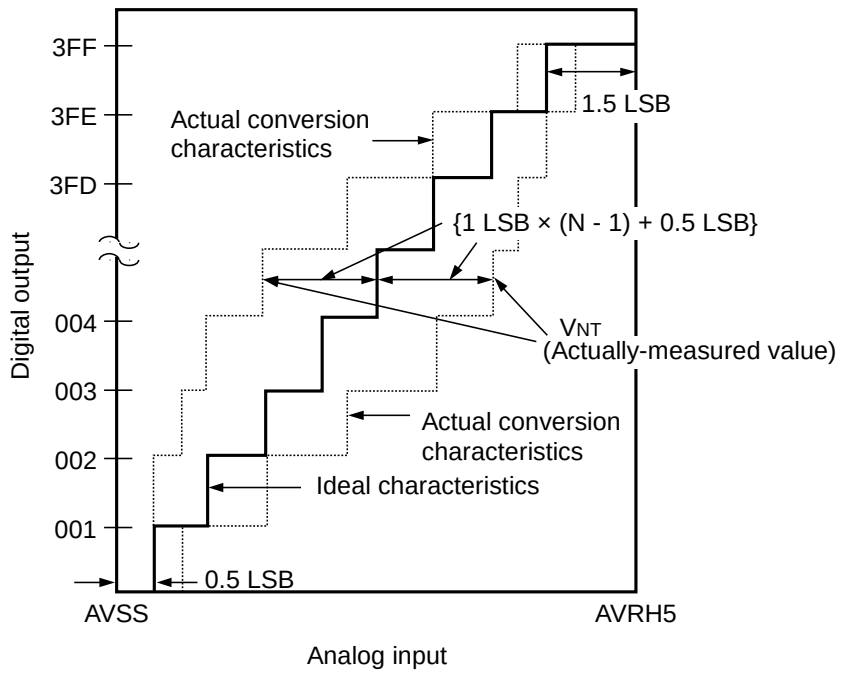
Be sure to use the clock with a frequency between 8MHz and 17MHz for the ADC compare clock in order to ensure its accuracy.

11.5.2 Definition of A/D Converter Terms

Resolution	:	Analog variation that is recognized by an A/D converter.
Non linearity error	:	Deviation of the actual conversion characteristics from a straight line that connects the zero transition point ("00 0000 0000"← →"00 0000 0001") to the full-scale transition point ("111111 1110"← →"11 1111 1111").
Differential linearity error	:	Deviation of the input voltage from the ideal value that is required to change the output code by LSB.
Total error	:	Difference between the actual value and the theoretical value. The total error includes zero transition error, full-scale transition error, and non linearity error.

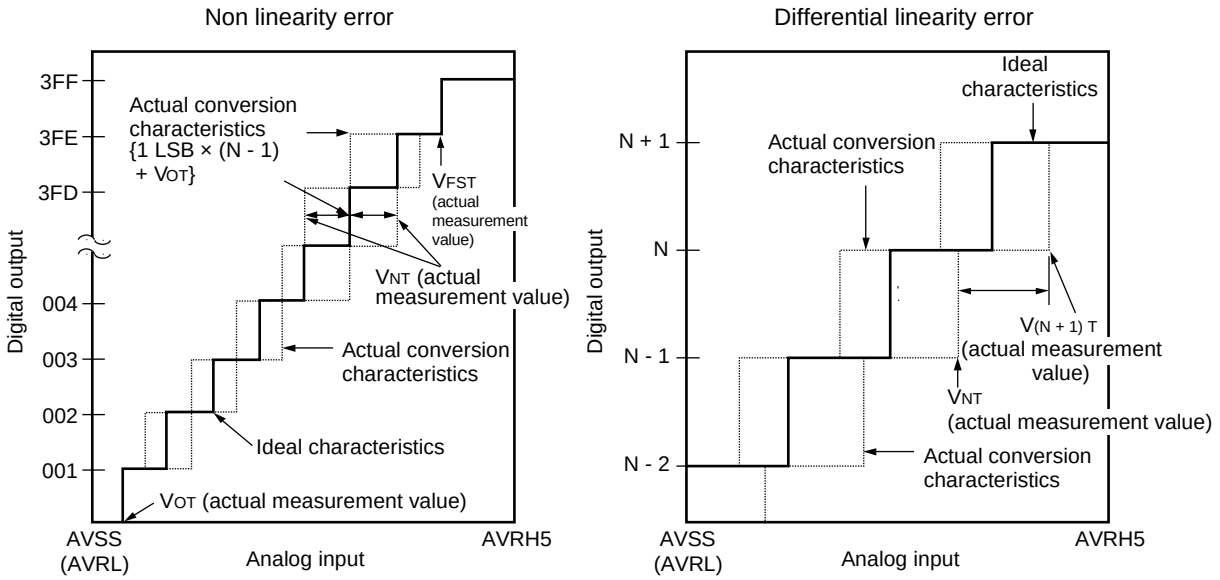
Total error



$$\text{Total error of digital output N} = \frac{V_{NT} - \{1LSB\} \times (N - 1) + 0.5LSB\}}{1LSB} \text{ [LSB]}$$

$$1LSB \text{ (Ideal value)} = \frac{AVRH5 - AVSS}{1024} \text{ [V]}$$

N: A/D converter digital output value.
V_{OT} (Ideal value) = AVSS + 0.5 LSB[V]
V_{FST} (Ideal value) = AVRH5 - 1.5 LSB[V]
V_{NT}: Voltage at which the digital output changes from (N - 1) to N.



$$\text{Linearity error of digital output N} = \frac{V_{NT} - \{1LSB\} \times (N - 1) + V_{OT}}{1LSB} \text{ [LSB]}$$

$$\text{Differential linearity error of digital output N} = \frac{V_{(N+1)T} - V_{NT}}{1LSB} - 1 \text{ [LSB]}$$

$$1LSB = \frac{V_{FST} - V_{OT}}{1022} \text{ [V]}$$

V_{OT} : Voltage at which the digital output changes from "000_H" to "001_H".
V_{FST} : Voltage at which the digital output changes from "$3FE_H$" to "$3FF_H$".

11.5.3 Notes on Using A/D Converter

<About the output impedance of the analog input of external circuit>

- External impedance values of the external input of 4.2 kΩ or lower (sampling time = 1.2 µs@ machine clock of 16 MHz) are recommended. When the external impedance is too high, the sampling time for analog voltages may not be sufficient. In this case, it is recommended to connect the capacitor (approx. 0.1 µF) to the analog input pin.

*1: The guaranteed value for erasure up to 100,000 cycles.

*2: Number of erase cycles for each sector.

*3: This value comes from the technology qualification (using Arrhenius equation to translate high temperature measurements into normalized value at + 85°C).

11.6.2 Notes

While the Flash memory is written or erased, shutdown of the external power (Vcc5) is prohibited.
In the application system where Vcc5 might be shut down while writing or erasing, be sure to turn the power off by using an external voltage detection function.
To put it concretely, after the external power supply voltage falls below the detection voltage (V_{DL}*), hold Vcc5 at 2.7V or more within the duration calculated by the following expression:

Td*[µs] + (period of PCLK [µs] x 257) + 50 [µs]
