

ABSOLUTE MAXIMUM RATINGS

(Voltages Referred to GND Pin)

Supply Voltage (V_{OUT}) -0.4V to 20V
 SW Pin Voltage -0.4V to 50V
 SHUTDOWN Pin Voltage 6.0V
 Maximum Power Dissipation 300mW

Operating Temperature Range 0°C to 70°C
 Storage Temperature Range -65°C to 150°C
 Lead Temperature (Soldering, 10 sec.) 300°C
 Switch Current 1.2A

LT1109-5, -12 N8, S8 Package

LT1109Z OPERATION

The LT1109Z-5 and LT1109Z-12 are fixed output voltage step-up DC/DC converters in a 3-pin TO-92 package. Power for internal regulator circuitry is taken from the V_{OUT} pin, a technique known as “bootstrapping.” Circuit operation can be best understood by referring to the block diagram. V_{OUT} , attenuated by $R1$ and $R2$, is applied to the negative input of comparator A1. When this voltage falls below the 1.25V reference voltage, the oscillator is turned on and the power switch Q1 cycles at the oscillator

frequency of 120kHz. Switch cycling alternately builds current in the inductor, then dumps it into the output capacitor, increasing the output voltage. When A1’s negative input rises above 1.25V, it turns off the oscillator. A small amount of hysteresis in A1 obviates the need for frequency compensation circuitry. When Q1 is off, current into the V_{OUT} pin drops to just 320 μ A. Quiescent current from the battery will be higher because the device operates off the *stepped-up* voltage.

LT1109 S8 AND N8 OPERATION

The 8-pin versions of the LT1109 have separate pins for V_{IN} and SENSE or FB and also have a SHUTDOWN pin. Separating the device V_{IN} pin from the SENSE pin allows the device to be powered from the (lower) input voltage rather than the (higher) output voltage. Although quiescent *current* remains constant, quiescent *power* will be

reduced by using the 8-pin version since the quiescent current flows from a lower voltage source. The SHUTDOWN pin disables the oscillator when taken to a logic "0." If left floating or tied high, the converter operates normally. With SHUTDOWN low, quiescent current remains at 320 μ A.

APPLICATIONS INFORMATION

Inductor Selection

A DC/DC converter operates by storing energy as magnetic flux in an inductor core, and then switching this energy into the load. To operate as an efficient energy transfer element, the inductor must fulfill three requirements. First, the inductance must be low enough for the inductor to store adequate energy under the worst case condition of minimum input voltage and switch-ON time. The inductance must also be high enough so that maximum current ratings of the LT1109 and inductor are not exceeded at the other worst case condition of maximum input voltage and ON time. Additionally, the inductor core must be able to store the required flux; i.e., it must not *saturate*. At power levels generally encountered with LT1109 designs, small ferrite surface-mount inductors will function well. Lastly, the inductor must have sufficiently low DC resistance so that excessive power is not lost as heat in the windings. Look for DCR values in the inductors' specification tables; values under 0.5 Ω will give best efficiency. An additional consideration is Electro-Magnetic Interference (EMI). Toroid and pot core type inductors are recommended in applications where EMI must be kept to a minimum; for example, where there are sensitive analog circuitry or transducers nearby. Rod core types are a less expensive choice where EMI is not a problem.

Specifying a proper inductor for an application requires first establishing minimum and maximum input voltage, output voltage, and output current. In a step-up converter, the inductive events add to the input voltage to produce the output voltage. Power required from the inductor is determined by

$$P_L = (V_{OUT} + V_D - V_{IN}) (I_{OUT}) \quad (01)$$

where V_D is the diode drop (0.5V for a 1N5818 Schottky). Energy required by the inductor per cycle must be equal or greater than

$$\frac{P_L}{F_{OSC}} \quad (02)$$

in order for the converter to regulate the output.

When the switch is closed, current in the inductor builds according to

$$I_L(t) = \frac{V_{IN}}{R'} \left(1 - e^{-\frac{R't}{L}} \right) \quad (03)$$

where R' is the sum of the switch equivalent resistance (0.8 typical at 25°C) and the inductor DC resistance. When the drop across the switch is small compared to V_{IN} , the simple lossless equation

$$I_L(t) = \frac{V_{IN}}{L} t \quad (04)$$

can be used. These equations assume that at $t = 0$, inductor current is zero. This situation is called "discontinuous mode operation" in switching regulator parlance. Setting "t" to the switch-ON time from the LT1109 specification table (typically 4.2 μ s) will yield I_{PEAK} for a specific "L" and V_{IN} . Once I_{PEAK} is known, energy in the inductor at the end of the switch-ON time can be calculated as

$$E_L = \frac{1}{2} L I_{PEAK}^2 \quad (05)$$

E_L must be greater than P_L/F_{OSC} for the converter to deliver the required power. For best efficiency I_{PEAK} should be

APPLICATIONS INFORMATION

kept to 600mA or less. Higher switch currents will cause excessive drop across the switch resulting in reduced efficiency. In general, switch current should be held to as low a value as possible in order to keep switch, diode and inductor losses at a minimum.

As an example, suppose 12V at 60mA is to be generated from a 4.5V input. Recalling Equation 01,

$$P_L = (12V + 0.5V - 4.5V) (60mA) = 480mW. \quad (06)$$

Energy required from the inductor is

$$\frac{P_L}{F_{OSC}} = \frac{480mW}{120kHz} = 4.0\mu J. \quad (07)$$

Picking an inductor value of 33 μ H with 0.2 Ω DCR results in a peak switch current of

$$I_{PEAK} = \frac{4.5V}{1.0\Omega} \left(1 - e^{-\frac{1.0 \cdot 4.2\mu s}{33\mu H}} \right) = 538mA. \quad (08)$$

Substituting I_{PEAK} into Equation 03 results in

$$E_L = \frac{1}{2} (33\mu H) (0.538A)^2 = 4.77\mu J. \quad (09)$$

Since 4.77 μ J > 4 μ J the 33 μ H inductor will work. This trial-and-error approach can be used to select the optimum inductor. Keep in mind the switch current maximum rating of 1.2A. If the calculated peak current exceeds this, the input voltage must be increased or the load decreased.

Capacitor Selection

The output capacitor should be chosen on the basis of its equivalent series resistance (ESR). Surface-mount tantalum electrolytics can be used provided the ESR value is sufficiently low. An ESR of 0.1 Ω will result in a 50mV step at the output of the converter when the peak inductor current is 500mA. Physically larger capacitors have lower ESR.

Diode Selection

Speed, forward drop, and leakage current are the three main considerations in selecting a catch diode for LT1109 converters. General purpose rectifiers such as the 1N4001

are *unsuitable* for use in *any* switching regulator application. Although they are rated at 1A, the switching time of a 1N4001 is in the 10 μ s-50 μ s range. At best, efficiency will be severely compromised when these diodes are used; at worst, the circuit may not work at all. Most LT1109 circuits will be well served by a 1N5818 Schottky diode. The combination of 500mV forward drop at 1A current, fast turn-ON and turn-OFF time, and 4 μ A to 10 μ A leakage current fit nicely with LT1109 requirements. At peak switch currents of 100mA or less, a 1N4148 signal diode may be used. This diode has leakage current in the 1nA to 5nA range at 25°C and lower cost than a 1N5818.
