Important Notes and Warnings

Micron Technology, Inc. ("Micron") reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions. This document supersedes and replaces all information supplied prior to the publication hereof. You may not rely on any information set forth in this document if you obtain the product described herein from any unauthorized distributor or other source not authorized by Micron.

Automotive Applications. Products are not designed or intended for use in automotive applications unless specifically designated by Micron as automotive-grade by their respective data sheets. Distributor and customer/distributor shall assume the sole risk and liability for and shall indemnify and hold Micron harmless against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, death, or property damage resulting directly or indirectly from any use of non-automotive-grade products in automotive applications. Customer/distributor shall ensure that the terms and conditions of sale between customer/distributor and any customer of distributor/customer (1) state that Micron products are not designed or intended for use in automotive applications unless specifically designated by Micron as automotive-grade by their respective data sheets and (2) require such customer of distributor/customer to indemnify and hold Micron harmless against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, death, or property damage resulting from any use of non-automotive-grade products in automotive applications.

Critical Applications. Products are not authorized for use in applications in which failure of the Micron component could result, directly or indirectly in death, personal injury, or severe property or environmental damage ("Critical Applications"). Customer must protect against death, personal injury, and severe property and environmental damage by incorporating safety design measures into customer's applications to ensure that failure of the Micron component will not result in such harms. Should customer or distributor purchase, use, or sell any Micron component for any critical application, customer and distributor shall indemnify and hold harmless Micron and its subsidiaries, subcontractors, and affiliates and the directors, officers, and employees of each against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, or death arising in any way out of such critical application, whether or not Micron or its subsidiaries, subcontractors, or affiliates were negligent in the design, manufacture, or warning of the Micron product.

Customer Responsibility. Customers are responsible for the design, manufacture, and operation of their systems, applications, and products using Micron products. ALL SEMICONDUCTOR PRODUCTS HAVE INHERENT FAILURE RATES AND LIMITED USEFUL LIVES. IT IS THE CUSTOMER'S SOLE RESPONSIBILITY TO DETERMINE WHETHER THE MICRON PRODUCT IS SUITABLE AND FIT FOR THE CUSTOMER'S SYSTEM, APPLICATION, OR PRODUCT. Customers must ensure that adequate design, manufacturing, and operating safeguards are included in customer's applications and products to eliminate the risk that personal injury, death, or severe property or environmental damages will result from failure of any semiconductor component.

Limited Warranty. In no event shall Micron be liable for any indirect, incidental, punitive, special or consequential damages (including without limitation lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort, warranty, breach of contract or other legal theory, unless explicitly stated in a written agreement executed by Micron's duly authorized representative.

Functional Description

The M25P10A is a 1Mb (125Kb x 8) serial Flash memory device with advanced write protection mechanisms accessed by a high-speed SPI-compatible bus.

The memory can be programmed 1 to 256 bytes at a time using the PAGE PROGRAM command. It is organized as 4 sectors, each containing 128 pages. Each page is 256 bytes wide. Memory can be viewed either as 512 pages or as 131,072 bytes. The entire memory can be erased using the BULK ERASE command, or it can be erased one sector at a time using the SECTOR ERASE command.

Figure 1: Logic Diagram

Table 1: Signal Names

Signal Name	Function	Direction
C	Serial clock	Input
DQ0	Serial data input	Input
DQ1	Serial data output	Output
S#	Chip select	Input
W#	Write protect	Input
HOLD#	Hold	Input
V _{CC}	Supply voltage	–
V _{SS}	Ground	–

Figure 2: Pin Connections: SO8, VFQFPN, and UFDFPN8

Note: 1. There is an exposed central pad on the underside of the MLP8 package that is pulled internally to V_{SS}, and must not be connected to any other voltage or signal line on the PCB. The Package Mechanical section provides information on package dimensions and how to identify pin 1.

Signal Descriptions

Table 2: Signal Descriptions

Signal	Type	Description
DQ1	Output	Serial data: The DQ1 output signal is used to transfer data serially out of the device. Data is shifted out on the falling edge of the serial clock (C).
DQ0	Input	Serial data: The DQ0 input signal is used to transfer data serially into the device. It receives commands, addresses, and the data to be programmed. Values are latched on the rising edge of the serial clock (C).
C	Input	Clock: The C input signal provides the timing of the serial interface. Commands, addresses, or data present at serial data input (DQ0) is latched on the rising edge of the serial clock (C). Data on DQ1 changes after the falling edge of C.
S#	Input	Chip select: When the S# input signal is HIGH, the device is deselected and DQ1 is at high impedance. Unless an internal PROGRAM, ERASE, or WRITE STATUS REGISTER cycle is in progress, the device will be in the standby power mode (not the deep power-down mode). Driving S# LOW enables the device, placing it in the active power mode. After power-up, a falling edge on S# is required prior to the start of any command.
HOLD#	Input	Hold: The HOLD# signal is used to pause any serial communications with the device without deselecting the device. During the hold condition, DQ1 is High-Z. DQ0 and C are "Don't Care." To start the hold condition, the device must be selected, with S# driven LOW.
W#/V _{PP}	Input	Write protect: The W#/V _{PP} signal is both a control input and a power supply pin. The two functions are selected by the voltage range applied to the pin. If the W#/V _{PP} input is kept in a low voltage range (0 V to V _{CC}) the pin is seen as a control input. The W# input signal is used to freeze the size of the area of memory that is protected against program or erase commands as specified by the values in BP2, BP1, and BP0 bits of the Status Register. V _{PP} acts as an additional power supply if it is in the range of V _{PPH} , as defined in the AC Measurement Conditions table. Avoid applying V _{PPH} to the W#/V _{PP} pin during a BULK ERASE operation.
V _{CC}	Power	Device core power supply: Source voltage.
V _{SS}	Ground	Ground: Reference for the V _{CC} supply voltage.
DNU	–	Do not use.

SPI Modes

These devices can be driven by a microcontroller with its serial peripheral interface (SPI) running in either of the following two SPI modes:

- CPOL = 0, CPHA = 0
- CPOL = 1, CPHA = 1

For these two modes, input data is latched in on the rising edge of serial clock (C), and output data is available from the falling edge of C.

The difference between the two modes is the clock polarity when the bus master is in standby mode and not transferring data:

- C remains at 0 for (CPOL = 0, CPHA = 0)
- C remains at 1 for (CPOL = 1, CPHA = 1)

Figure 3: SPI Modes Supported

Because only one device is selected at a time, only one device drives the serial data output (DQ1) line at a time, while the other devices are High-Z. An example of three devices connected to an MCU on an SPI bus is shown here.

[illegible]

- Notes:
1. WRITE PROTECT (W#) and HOLD# should be driven HIGH or LOW as appropriate.
 2. Resistors (R) ensure that the memory device is not selected if the bus master leaves the S# line High-Z.
 3. The bus master may enter a state where all I/O are High-Z at the same time; for example, when the bus master is reset. Therefore, C must be connected to an external pull-down resistor so that when all I/O are High-Z, S# is pulled HIGH while C is pulled LOW. This ensures that S# and C do not go HIGH at the same time and that the t_{SHCH} requirement is met.
 4. The typical value of R is 100k Ω , assuming that the time constant $R \times C_p$ (C_p = parasitic capacitance of the bus line) is shorter than the time during which the bus master leaves the SPI bus High-Z.
 5. Example: Given that $C_p = 50\text{pF}$ ($R \times C_p = 5\mu\text{s}$), the application must ensure that the bus master never leaves the SPI bus High-Z for a time period shorter than 5 μs .

Operating Features

Page Programming

To program one data byte, two commands are required: WRITE ENABLE, which is one byte, and a PAGE PROGRAM sequence, which is four bytes plus data. This is followed by the internal PROGRAM cycle of duration t_{PP} . To spread this overhead, the PAGE PROGRAM command allows up to 256 bytes to be programmed at a time (changing bits from 1 to 0), provided they lie in consecutive addresses on the same page of memory. To optimize timings, it is recommended to use the PAGE PROGRAM command to program all consecutive targeted bytes in a single sequence than to use several PAGE PROGRAM sequences with each containing only a few bytes.

Sector Erase, Bulk Erase

The PAGE PROGRAM command allows bits to be reset from 1 to 0. Before this can be applied, the bytes of memory need to have been erased to all 1s (FFh). This can be achieved a sector at a time using the SECTOR ERASE command, or throughout the entire memory using the BULK ERASE command. This starts an internal ERASE cycle of duration t_{SE} or t_{BE} . The ERASE command must be preceded by a WRITE ENABLE command.

Polling during a Write, Program, or Erase Cycle

An improvement in the time to complete the following commands can be achieved by not waiting for the worst case delay (t_W , t_{PP} , t_{SE} , or t_{BE}).

- WRITE STATUS REGISTER
- PROGRAM
- ERASE (SECTOR ERASE, BULK ERASE)

The write in progress (WIP) bit is provided in the status register so that the application program can monitor this bit in the status register, polling it to establish when the previous WRITE cycle, PROGRAM cycle, or ERASE cycle is complete.

Active Power, Standby Power, and Deep Power-Down

When chip select ($S\#$) is LOW, the device is selected, and in the ACTIVE POWER mode. When $S\#$ is HIGH, the device is deselected, but could remain in the ACTIVE POWER mode until all internal cycles have completed (PROGRAM, ERASE, WRITE STATUS REGISTER). The device then goes in to the STANDBY POWER mode. The device consumption drops to I_{CC1} .

The DEEP POWER-DOWN mode is entered when the DEEP POWER-DOWN command is executed. The device consumption drops further to I_{CC2} . The device remains in this mode until the RELEASE FROM DEEP POWER-DOWN command is executed. While in the DEEP POWER-DOWN mode, the device ignores all WRITE, PROGRAM, and ERASE commands. This provides an extra software protection mechanism when the device is not in active use, by protecting the device from inadvertent WRITE, PROGRAM, or ERASE operations. For further information, see the DEEP POWER DOWN command.

Status Register

The status register contains a number of status and control bits that can be read or set (as appropriate) by specific commands. For a detailed description of the status register bits, see READ STATUS REGISTER (page 24).

Data Protection by Protocol

Non-volatile memory is used in environments that can include excessive noise. The following capabilities help protect data in these noisy environments.

Power on reset and an internal timer (t_{PUW}) can provide protection against inadvertent changes while the power supply is outside the operating specification.

PROGRAM, ERASE, and WRITE STATUS REGISTER commands are checked before they are accepted for execution to ensure they consist of a number of clock pulses that is a multiple of eight.

All commands that modify data must be preceded by a WRITE ENABLE command to set the write enable latch (WEL) bit.

In addition to the low power consumption feature, the DEEP POWER-DOWN mode offers extra software protection since all PROGRAM, and ERASE commands are ignored when the device is in this mode.

Software Data Protection

Memory can be configured as read-only using the block protect bits (BP2, BP1, BP0) as shown in the Protected Area Sizes table.

Hardware Data Protection

Hardware data protection is implemented using the write protect signal applied on the W# pin. This freezes the status register in a read-only mode. In this mode, the block protect (BP) bits and the status register write disable bit (SRWD) are protected.

Table 3: Protected Area Sizes

Status Register Content		Memory Content	
BP Bit 1	BP Bit 0	Protected Area	Unprotected Area
0	0	none	All sectors (sectors 0 to 3)
0	1	Upper 4th (sector 3)	Lower 3/4ths (sectors 0 to 2)
1	0	Upper half (sectors 2 and 3)	Lower half (sectors 0 and 1)
1	1	All sectors (sectors 0 to 3)	none

Note: 1. 0 0 = unprotected area (sectors): The device is ready to accept a BULK ERASE command only if all block protect bits (BP1, BP0) are 0.

Table 4: Protected Area Sizes

1	1	1	All sectors (sectors 0 to 63)	none

Note: 1. 0 0 0 = unprotected area (sectors): The device is ready to accept a BULK ERASE command only if all block protect bits (BP2, BP1, BP0) are 0.

Table 8: Protected Area Sizes

Status Register Content			Memory Content	
BP Bit 2	BP Bit 1	BP Bit 0	Protected Area	Unprotected Area
0	0	0	none	All sectors (sectors 0 to 127)
0	0	1	Upper 64th (sectors 126 and 127)	Lower 63/64ths (sectors 0 to 125)
0	1	0	Upper 32nd (sectors 124 to 127)	Lower 31/32nds (sectors 0 to 123)
0	1	1	Upper 16th (sectors 120 to 127)	Lower 15/16ths (sectors 0 to 119)
1	0	0	Upper 8th (sectors 112 to 127)	Lower 7/8ths (sectors 0 to 111)
1	0	1	Upper 4th (sectors 96 to 127)	Lower 3/4ths (sectors 0 to 95)
1	1	0	Upper half (sectors 64 to 127)	Lower half (sectors 0 to 63)
1	1	1	All sectors (sectors 0 to 127)	none

Note: 1. The device is ready to accept a BULK ERASE command only if all block protect bits (BP2, BP1, BP0) are 0.

Hold Condition

The HOLD# signal is used to pause any serial communications with the device without resetting the clocking sequence. However, taking this signal LOW does not terminate any WRITE STATUS REGISTER, PROGRAM, or ERASE cycle that is currently in progress.

To enter the hold condition, the device must be selected, with S# LOW. The hold condition starts on the falling edge of the HOLD# signal, if this coincides with serial clock (C) being LOW. The hold condition ends on the rising edge of the HOLD# signal, if this coincides with C being LOW. If the falling edge does not coincide with C being LOW, the hold condition starts after C next goes LOW. Similarly, if the rising edge does not coincide with C being LOW, the hold condition ends after C next goes LOW.

During the hold condition, DQ1 is HIGH impedance while DQ0 and C are Don't Care. Typically, the device remains selected with S# driven LOW for the duration of the hold condition. This ensures that the state of the internal logic remains unchanged from the moment of entering the hold condition. If S# goes HIGH while the device is in the hold condition, the internal logic of the device is reset. To restart communication with the device, it is necessary to drive HOLD# HIGH, and then to drive S# LOW. This prevents the device from going back to the hold condition.

Figure 5: Hold Condition Activation

Configuration and Memory Map

Memory Configuration and Block Diagram

Each page of memory can be individually programmed; bits are programmed from 1 to 0. The device is sector or bulk-erasable, but not page-erasable; bits are erased from 0 to 1. The memory is configured as follows:

- 131,072 bytes (8 bits each)
- 4 sectors (256Kb, 32,768 bytes each)
- 512 pages (256 bytes each)

Figure 6: Block Diagram

Memory Map – 1Mb Density

Table 9: Sectors 3:0

Sector	Address Range	
	Start	End
3	0001 8000	0001 FFFF
2	0001 0000	0001 7FFF
1	0008 0000	0000 FFFF
0	0000 0000	0000 7FFF

Command Set Overview

All commands, addresses, and data are shifted in and out of the device, most significant bit first.

Serial data input DQ0 is sampled on the first rising edge of serial clock (C) after chip select (S#) is driven LOW. Then, the one-byte command code must be shifted in to the device, most significant bit first, on DQ1, each bit being latched on the rising edges of C.

Every command sequence starts with a one-byte command code. Depending on the command, this command code might be followed by address or data bytes, by address and data bytes, or by neither address or data bytes. For the following commands, the shifted-in command sequence is followed by a data-out sequence. S# can be driven HIGH after any bit of the data-out sequence is being shifted out.

- READ DATA BYTES (READ)
- READ DATA BYTES at HIGHER SPEED
- READ STATUS REGISTER
- READ IDENTIFICATION
- RELEASE from DEEP POWER-DOWN

For the following commands, S# must be driven HIGH exactly at a byte boundary. That is, after an exact multiple of eight clock pulses following S# being driven LOW, S# must be driven HIGH. Otherwise, the command is rejected and not executed.

- PAGE PROGRAM
- SECTOR ERASE
- BULK ERASE
- WRITE STATUS REGISTER
- WRITE ENABLE
- WRITE DISABLE
- DEEP POWER-DOWN

All attempts to access the memory array are ignored during a WRITE STATUS REGISTER command cycle, a PROGRAM command cycle, or an ERASE command cycle. In addition, the internal cycle for each of these commands continues unaffected.

Table 10: Command Set Codes

Command Name	One-Byte Command Code		Bytes		
			Address	Dummy	Data
WRITE ENABLE	0000 0110	06h	0	0	0
WRITE DISABLE	0000 0100	04h	0	0	0
READ IDENTIFICATION	1001 1111	9Fh	0	0	1 to 20
	1001 1110	9Eh			1 to 20
READ STATUS REGISTER	0000 0101	05h	0	0	1 to ∞
WRITE STATUS REGISTER	0000 0001	01h	0	0	1
READ DATA BYTES	0000 0011	03h	3	0	1 to ∞
READ DATA BYTES at HIGHER SPEED	0000 1011	0Bh	3	1	1 to ∞
PAGE PROGRAM	0000 0010	02h	3	0	1 to 256
SECTOR ERASE	1101 1000	D8h	3	0	0
BULK ERASE	1100 0111	C7h	0	0	0
DEEP POWER-DOWN	1011 1001	B9h	0	0	0
RELEASE from DEEP POWER-DOWN	1010 1011	ABh	0	0	0

WRITE ENABLE

The WRITE ENABLE command sets the write enable latch (WEL) bit.

The WEL bit must be set before execution of every PROGRAM, ERASE, and WRITE command.

The WRITE ENABLE command is entered by driving chip select (S#) LOW, sending the command code, and then driving S# HIGH.

Figure 7: WRITE ENABLE Command Sequence

WRITE DISABLE

The WRITE DISABLE command resets the write enable latch (WEL) bit.

The WRITE DISABLE command is entered by driving chip select (S#) LOW, sending the command code, and then driving S# HIGH.

The WEL bit is reset under the following conditions:

- Power-up
- Completion of any ERASE operation
- Completion of any PROGRAM operation
- Completion of any WRITE STATUS REGISTER operation
- Completion of WRITE DISABLE operation

Figure 8: WRITE DISABLE Command Sequence

READ IDENTIFICATION

The READ IDENTIFICATION command reads the following device identification data:

- Manufacturer identification (1 byte): This is assigned by JEDEC.
- Device identification (2 bytes): This is assigned by device manufacturer; the first byte indicates memory type and the second byte indicates device memory capacity.
- A Unique ID code (UID) (17 bytes, 16 available upon customer request): The first byte contains length of data to follow; the remaining 16 bytes contain optional Customized Factory Data (CFD) content.

Table 11: READ IDENTIFICATION Data Out Sequence

Manufacturer Identification	Device Identification		UID	
	Memory Type	Memory Capacity	CFD Length	CFD Content
20h	20h	11h	10h	16 bytes
		13h		
		14h		
		15h		
		16h		
		17h		
		18h		

Note: 1. The CFD bytes are read-only and can be programmed with customer data upon demand. If customers do not make requests, the devices are shipped with all the CFD bytes programmed to zero.

A READ IDENTIFICATION command is not decoded while an ERASE or PROGRAM cycle is in progress and has no effect on a cycle in progress. The READ IDENTIFICATION command must not be issued while the device is in DEEP POWER-DOWN mode.

The device is first selected by driving S# LOW. Then the 8-bit command code is shifted in and content is shifted out on DQ1 as follows: the 24-bit device identification that is stored in the memory, the 8-bit CFD length, followed by 16 bytes of CFD content. Each bit is shifted out during the falling edge of serial clock (C).

The READ IDENTIFICATION command is terminated by driving S# HIGH at any time during data output. When S# is driven HIGH, the device is put in the STANDBY POWER mode and waits to be selected so that it can receive, decode, and execute commands.

Figure 9: READ IDENTIFICATION Command Sequence

READ STATUS REGISTER

The READ STATUS REGISTER command allows the status register to be read. The status register may be read at any time, even while a PROGRAM, ERASE, or WRITE STATUS REGISTER cycle is in progress. When one of these cycles is in progress, it is recommended to check the write in progress (WIP) bit before sending a new command to the device. It is also possible to read the status register continuously.

Figure 10: READ STATUS REGISTER Command Sequence

Figure 11: Status Register Format

Figure 12: Status Register Format

WIP Bit

The write in progress (WIP) bit indicates whether the memory is busy with a WRITE STATUS REGISTER cycle, a PROGRAM cycle, or an ERASE cycle. When the WIP bit is set to 1, a cycle is in progress; when the WIP bit is set to 0, a cycle is not in progress.

WEL Bit

The write enable latch (WEL) bit indicates the status of the internal write enable latch. When the WEL bit is set to 1, the internal write enable latch is set; when the WEL bit is set to 0, the internal write enable latch is reset and no WRITE STATUS REGISTER, PROGRAM, or ERASE command is accepted.

Block Protect Bits

The block protect bits are non-volatile. They define the size of the area to be software protected against PROGRAM and ERASE commands. The block protect bits are written with the WRITE STATUS REGISTER command.

When one or more of the block protect bits is set to 1, the relevant memory area, as defined in the Protected Area Sizes table, becomes protected against PAGE PROGRAM and SECTOR ERASE commands. The block protect bits can be written provided that the hardware protected mode has not been set. The BULK ERASE command is executed only if all block protect bits are 0.

SRWD Bit

The status register write disable (SRWD) bit is operated in conjunction with the write protect ($W\#/V_{PP}$) signal. When the SRWD bit is set to 1 and $W\#/V_{PP}$ is driven LOW, the device is put in the hardware protected mode. In the hardware protected mode, the non-volatile bits of the status register (SRWD, and the block protect bits) become read-only bits and the WRITE STATUS REGISTER command is no longer accepted for execution.

WRITE STATUS REGISTER

The WRITE STATUS REGISTER command allows new values to be written to the status register. Before the WRITE STATUS REGISTER command can be accepted, a WRITE ENABLE command must have been executed previously. After the WRITE ENABLE command has been decoded and executed, the device sets the write enable latch (WEL) bit.

The WRITE STATUS REGISTER command is entered by driving chip select (S#) LOW, followed by the command code and the data byte on serial data input (DQ0). The WRITE STATUS REGISTER command has no effect on b6, b5, b4, b1, and b0 of the status register. The status register b6, b5, and b4 are always read as "0". S# must be driven HIGH after the eighth bit of the data byte has been latched in. If not, the WRITE STATUS REGISTER command is not executed.

Figure 13: WRITE STATUS REGISTER Command Sequence

As soon as S# is driven HIGH, the self-timed WRITE STATUS REGISTER cycle is initiated; its duration is t_W . While the WRITE STATUS REGISTER cycle is in progress, the status register may still be read to check the value of the write in progress (WIP) bit. The WIP bit is 1 during the self-timed WRITE STATUS REGISTER cycle, and is 0 when the cycle is completed. Also, when the cycle is completed, the WEL bit is reset.

The WRITE STATUS REGISTER command allows the user to change the values of the block protect bits (BP2, BP1, BP0). Setting these bit values defines the size of the area that is to be treated as read-only, as defined in the Protected Area Sizes table.

The WRITE STATUS REGISTER command also allows the user to set and reset the status register write disable (SRWD) bit in accordance with the write protect (W#/V_{PP}) signal. The SRWD bit and the W#/V_{PP} signal allow the device to be put in the hardware protected (HPM) mode. The WRITE STATUS REGISTER command is not executed once the HPM is entered. The options for enabling the status register protection modes are summarized here.

Table 12: Status Register Protection Modes

W#/V _{pp} Signal	SRWD Bit	Protection Mode (PM)	Status Register Write Protection	Memory Content		Notes
				Protected Area	Unprotected Area	
1	0	Software protected mode (SPM)	Software protection	Commands not accepted	Commands accepted	1, 2, 3
0	0					
1	1					
0	1	Hardware protected mode (HPM)	Hardware protection	Commands not accepted	Commands accepted	3, 4, 5,

- Notes:
1. Software protection: status register is writable (SRWD, BP2, BP1, and BP0 bit values can be changed) if the WRITE ENABLE command has set the WEL bit.
 2. PAGE PROGRAM, SECTOR ERASE, and BULK ERASE commands are not accepted.
 3. PAGE PROGRAM and SECTOR ERASE commands can be accepted.
 4. Hardware protection: status register is not writable (SRWD, BP2, BP1, and BP0 bit values cannot be changed).
 5. PAGE PROGRAM, SECTOR ERASE, and BULK ERASE commands are not accepted.

When the SRWD bit of the status register is 0 (its initial delivery state), it is possible to write to the status register provided that the WEL bit has been set previously by a WRITE ENABLE command, regardless of whether the W#/V_{pp} signal is driven HIGH or LOW. When the status register SRWD bit is set to 1, two cases need to be considered depending on the state of the W#/V_{pp} signal:

- If the W#/V_{pp} signal is driven HIGH, it is possible to write to the status register provided that the WEL bit has been set previously by a WRITE ENABLE command.
- If the W#/V_{pp} signal is driven LOW, it is not possible to write to the status register even if the WEL bit has been set previously by a WRITE ENABLE command. Therefore, attempts to write to the status register are rejected, and are not accepted for execution. The result is that all the data bytes in the memory area that have been put in SPM by the status register block protect bits (BP2, BP1, BP0) are also hardware protected against data modification.

Regardless of the order of the two events, the HPM can be entered in either of the following ways:

- Setting the status register SRWD bit after driving the W#/V_{pp} signal LOW
- Driving the W#/V_{pp} signal LOW after setting the status register SRWD bit.

The only way to exit the HPM is to pull the W#/V_{pp} signal HIGH. If the W#/V_{pp} signal is permanently tied HIGH, the HPM can never be activated. In this case, only the SPM is available, using the status register block protect bits (BP2, BP1, BP0).

The device is first selected by driving chip select (S#) LOW. The command code for READ DATA BYTES is followed by a 3-byte address (A23-A0), each bit being latched-in during the rising edge of serial clock (C). Then the memory contents at that address is shifted out on serial data output (DQ1), each bit being shifted out at a maximum frequency f_R during the falling edge of C.

The first byte addressed can be at any location. The address is automatically incremented to the next higher address after each byte of data is shifted out. Therefore, the entire memory can be read with a single READ DATA BYTES command. When the highest address is reached, the address counter rolls over to 000000h, allowing the read sequence to be continued indefinitely.

The READ DATA BYTES command is terminated by driving S# HIGH. S# can be driven HIGH at any time during data output. Any READ DATA BYTES command issued while an ERASE, PROGRAM, or WRITE cycle is in progress is rejected without any effect on the cycle that is in progress.

Timing diagram for the 16-bit parallel data bus. The diagram shows three signals: C (clock), DQ[0] (data bus), and DQ1 (data bus). The clock signal C has a period of 10 units, with a high pulse of 7 units and a low pulse of 3 units. The data bus DQ[0] is divided into three sections: a Command section (MSB to LSB) from clock cycle 0 to 7, an Address section (A[MIN] to A[MAX]) from clock cycle 8 to C_x, and a Data section (D_{OUT}) from clock cycle C_x to the end. The data bus DQ1 is High-Z from clock cycle 0 to 7, then outputs D_{OUT} from clock cycle C_x to the end. A legend indicates that the hatched area represents 'Don't Care'.

Note: 1. $C_x = 7 + (A[\text{MAX}] + 1)$.

READ DATA BYTES at HIGHER SPEED

The device is first selected by driving chip select (S#) LOW. The command code for the READ DATA BYTES at HIGHER SPEED command is followed by a 3-byte address (A23-A0) and a dummy byte, each bit being latched-in during the rising edge of serial clock (C). Then the memory contents at that address are shifted out on serial data output (DQ1) at a maximum frequency f_C , during the falling edge of C.

The first byte addressed can be at any location. The address is automatically incremented to the next higher address after each byte of data is shifted out. Therefore, the entire memory can be read with a single READ DATA BYTES at HIGHER SPEED command. When the highest address is reached, the address counter rolls over to 000000h, allowing the read sequence to be continued indefinitely.

The READ DATA BYTES at HIGHER SPEED command is terminated by driving S# HIGH. S# can be driven HIGH at any time during data output. Any READ DATA BYTES at HIGHER SPEED command issued while an ERASE, PROGRAM, or WRITE cycle is in progress is rejected without any effect on the cycle that is in progress.

Figure 15: READ DATA BYTES at HIGHER SPEED Command Sequence

Note: 1. $C_x = 7 + (A[23] + 1)$.

The PAGE PROGRAM command allows bytes in the memory to be programmed, which means the bits are changed from 1 to 0. Before a PAGE PROGRAM command can be accepted a WRITE ENABLE command must be executed. After the WRITE ENABLE command has been decoded, the device sets the write enable latch (WEL) bit.

If the eight least significant address bits (A7-A0) are not all zero, all transmitted data that goes beyond the end of the current page are programmed from the start address of the same page; that is, from the address whose eight least significant bits (A7-A0) are all zero. *S#* must be driven LOW for the entire duration of the sequence.

For optimized timings, it is recommended to use the PAGE PROGRAM command to program all consecutive targeted bytes in a single sequence rather than to use several PAGE PROGRAM sequences, each containing only a few bytes.

As soon as $S\#$ is driven HIGH, the self-timed PAGE PROGRAM cycle is initiated; the cycles's duration is t_{pp} . While the PAGE PROGRAM cycle is in progress, the status register may be read to check the value of the write in progress (WIP) bit. The WIP bit is 1 during the self-timed PAGE PROGRAM cycle, and 0 when the cycle is completed. At some unspecified time before the cycle is completed, the write enable latch (WEL) bit is reset.

Figure 16: PAGE PROGRAM Command Sequence

Note: 1. $C_x = 7 + (A[\text{MAX}] + 1)$.

SECTOR ERASE

The SECTOR ERASE command sets to 1 (FFh) all bits inside the chosen sector. Before the SECTOR ERASE command can be accepted, a WRITE ENABLE command must have been executed previously. After the WRITE ENABLE command has been decoded, the device sets the write enable latch (WEL) bit.

The SECTOR ERASE command is entered by driving chip select (S#) LOW, followed by the command code, and three address bytes on serial data input (DQ0). Any address inside the sector is a valid address for the SECTOR ERASE command. S# must be driven LOW for the entire duration of the sequence.

S# must be driven HIGH after the eighth bit of the last address byte has been latched in. Otherwise the SECTOR ERASE command is not executed. As soon as S# is driven HIGH, the self-timed SECTOR ERASE cycle is initiated; the cycle's duration is t_{SE} . While the SECTOR ERASE cycle is in progress, the status register may be read to check the value of the write in progress (WIP) bit. The WIP bit is 1 during the self-timed SECTOR ERASE cycle, and is 0 when the cycle is completed. At some unspecified time before the cycle is completed, the WEL bit is reset.

A SECTOR ERASE command is not executed if it applies to a sector that is hardware or software protected.

Figure 17: SECTOR ERASE Command Sequence

Note: 1. $C_x = 7 + (A[15] + 1)$.

BULK ERASE

The BULK ERASE command sets all bits to 1 (FFh). Before the BULK ERASE command can be accepted, a WRITE ENABLE command must have been executed previously. After the WRITE ENABLE command has been decoded, the device sets the write enable latch (WEL) bit.

The BULK ERASE command is entered by driving chip select (S#) LOW, followed by the command code on serial data input (DQ0). S# must be driven LOW for the entire duration of the sequence.

S# must be driven HIGH after the eighth bit of the command code has been latched in. Otherwise the BULK ERASE command is not executed. As soon as S# is driven HIGH, the self-timed BULK ERASE cycle is initiated; the cycle's duration is t_{BE} . While the BULK ERASE cycle is in progress, the status register may be read to check the value of the write In progress (WIP) bit. The WIP bit is 1 during the self-timed BULK ERASE cycle, and is 0 when the cycle is completed. At some unspecified time before the cycle is completed, the WEL bit is reset.

The BULK ERASE command is executed only if all block protect (BP2, BP1, BP0) bits are 0. The BULK ERASE command is ignored if one or more sectors are protected.

Figure 18: BULK ERASE Command Sequence

DEEP POWER-DOWN

Executing the DEEP POWER-DOWN command is the only way to put the device in the lowest power consumption mode, the DEEP POWER-DOWN mode. The DEEP POWER-DOWN command can also be used as a software protection mechanism while the device is not in active use because in the DEEP POWER-DOWN mode the device ignores all WRITE, PROGRAM, and ERASE commands.

Driving chip select (S#) HIGH deselects the device, and puts it in the STANDBY POWER mode if there is no internal cycle currently in progress. Once in STANDBY POWER mode, the DEEP POWER-DOWN mode can be entered by executing the DEEP POWER-DOWN command, subsequently reducing the standby current from I_{CC1} to I_{CC2} .

To take the device out of DEEP POWER-DOWN mode, the RELEASE from DEEP POWER-DOWN command must be issued. Other commands must not be issued while the device is in DEEP POWER-DOWN mode. The DEEP POWER-DOWN mode stops automatically at power-down. The device always powers up in STANDBY POWER mode.

The DEEP POWER-DOWN command is entered by driving S# LOW, followed by the command code on serial data input (DQ0). S# must be driven LOW for the entire duration of the sequence.

S# must be driven HIGH after the eighth bit of the command code has been latched in. Otherwise the DEEP POWER-DOWN command is not executed. As soon as S# is driven HIGH, it requires a delay of t_{DP} before the supply current is reduced to I_{CC2} and the DEEP POWER-DOWN mode is entered.

Any DEEP POWER-DOWN command issued while an ERASE, PROGRAM, or WRITE cycle is in progress is rejected without any effect on the cycle that is in progress.

Figure 19: DEEP POWER-DOWN Command Sequence

RELEASE from DEEP POWER-DOWN

Once the device has entered DEEP POWER-DOWN mode, all commands are ignored except RELEASE from DEEP POWER-DOWN and READ ELECTRONIC SIGNATURE. Executing either of these commands takes the device out of the DEEP POWER-DOWN mode.

The RELEASE from DEEP POWER-DOWN command is entered by driving chip select (S#) LOW, followed by the command code on serial data input (DQ0). S# must be driven LOW for the entire duration of the sequence.

The RELEASE from DEEP POWER-DOWN command is terminated by driving S# HIGH. Sending additional clock cycles on serial clock C while S# is driven LOW causes the command to be rejected and not executed.

After S# has been driven HIGH, followed by a delay, t_{RES} , the device is put in the STANDBY mode. S# must remain HIGH at least until this period is over. The device waits to be selected so that it can receive, decode, and execute commands.

Any RELEASE from DEEP POWER-DOWN command issued while an ERASE, PROGRAM, or WRITE cycle is in progress is rejected without any effect on the cycle that is in progress.

Figure 20: RELEASE from DEEP POWER-DOWN Command Sequence

READ ELECTRONIC SIGNATURE

Once the device enters DEEP POWER-DOWN mode, all commands are ignored except READ ELECTRONIC SIGNATURE and RELEASE from DEEP POWER-DOWN. Executing either of these commands takes the device out of the DEEP POWER-DOWN mode.

The READ ELECTRONIC SIGNATURE command is entered by driving chip select (S#) LOW, followed by the command code and three dummy bytes on serial data input (DQ0). Each bit is latched in on the rising edge of serial clock C. The 8-bit electronic signature is shifted out on serial data output DQ1 on the falling edge of C; S# must be driven LOW the entire duration of the sequence for the electronic signature to be read. However, driving S# HIGH after the command code, but before the entire 8-bit electronic signature has been output for the first time, still ensures that the device is put into STANDBY mode.

Except while an ERASE, PROGRAM, or WRITE STATUS REGISTER cycle is in progress, the READ ELECTRONIC SIGNATURE command provides access to the 8-bit electronic signature of the device, and can be applied even if DEEP POWER-DOWN mode has not been entered. The READ ELECTRONIC SIGNATURE command is not executed while an ERASE, PROGRAM, or WRITE STATUS REGISTER cycle is in progress and has no effect on the cycle in progress.

The READ ELECTRONIC SIGNATURE command is terminated by driving S# high after the electronic signature has been read at least once. Sending additional clock cycles C while S# is driven LOW causes the electronic signature to be output repeatedly.

If S# is driven HIGH, the device is put in STANDBY mode immediately unless it was previously in DEEP POWER-DOWN mode. If previously in DEEP POWER-DOWN mode, the device transitions to STANDBY mode with delay as described here. Once in STANDBY mode, the device waits to be selected so that it can receive, decode, and execute instructions.

- If S# is driven HIGH before the electronic signature is read, transition to STANDBY mode is delayed by tRES1, as shown in the RELEASE from DEEP POWER-DOWN command sequence. S# must remain HIGH for at least tRES1(max).
- If S# is driven HIGH after the electronic signature is read, transition to STANDBY mode is delayed by tRES2. S# must remain HIGH for at least tRES2(max).

Figure 21: READ ELECTRONIC SIGNATURE Command Sequence

Note: 1. $C_x = 7 + (A[\text{MAX}] + 1)$.

Power-Up/Down and Supply Line Decoupling

At power-up and power-down, the device must not be selected; that is, chip select (S#) must follow the voltage applied on V_{CC} until V_{CC} reaches the correct value:

- $V_{CC,min}$ at power-up, and then for a further delay of t_{VSL}
- V_{SS} at power-down

A safe configuration is provided in the SPI Modes section.

To avoid data corruption and inadvertent write operations during power-up, a power-on-reset (POR) circuit is included. The logic inside the device is held reset while V_{CC} is less than the POR threshold voltage, V_{WI} – all operations are disabled, and the device does not respond to any instruction. Moreover, the device ignores the following instructions until a time delay of t_{PUW} has elapsed after the moment that V_{CC} rises above the V_{WI} threshold:

- WRITE ENABLE
- PAGE PROGRAM
- SECTOR ERASE
- BULK ERASE
- WRITE STATUS REGISTER

However, the correct operation of the device is not guaranteed if, by this time, V_{CC} is still below $V_{CC,min}$. No WRITE STATUS REGISTER, PROGRAM, or ERASE instruction should be sent until:

- t_{PUW} after V_{CC} has passed the V_{WI} threshold
- t_{VSL} after V_{CC} has passed the $V_{CC,min}$ level

If the time, t_{VSL} , has elapsed, after V_{CC} rises above $V_{CC,min}$, the device can be selected for READ instructions even if the t_{PUW} delay has not yet fully elapsed.

V_{PPH} must be applied only when V_{CC} is stable and in the $V_{CC,min}$ to $V_{CC,max}$ voltage range.

Figure 22: Power-Up Timing

After power-up, the device is in the following state:

- Standby power mode (not the deep power-down mode)
- Write enable latch (WEL) bit is reset
- Write in progress (WIP) bit is reset
- Write lock bit = 0
- Lock down bit = 0

Normal precautions must be taken for supply line decoupling to stabilize the V_{CC} supply. Each device in a system should have the V_{CC} line decoupled by a suitable capacitor close to the package pins; generally, this capacitor is of the order of 100 nF.

At power-down, when V_{CC} drops from the operating voltage to below the POR threshold voltage V_{WL} , all operations are disabled and the device does not respond to any instruction.

Note: If power-down occurs while a WRITE, PROGRAM, or ERASE cycle is in progress, some data corruption may result.

Power-Up Timing and Write Inhibit Voltage Threshold Specifications

Table 13: Power-Up Timing and V_{WI} Threshold

Symbol	Parameter	Min	Max	Unit
t_{VSL}	$V_{CC}(\text{min})$ to S# LOW	10	–	μs
t_{PUW}	Time delay to write instruction	1.0	10	ms
V_{WI}	Write Inhibit voltage (grade 6)	1.0	2.0	V
V_{WI}	Write Inhibit voltage (grade 3)	1.0	2.2	V

Note: 1. Parameters are characterized only.

If the time, t_{VSL} , has elapsed, after V_{CC} rises above $V_{CC}(\text{min})$, the device can be selected for READ instructions even if the t_{PUW} delay has not yet fully elapsed.

V_{PPH} must be applied only when V_{CC} is stable and in the $V_{CC\text{min}}$ to $V_{CC\text{max}}$ voltage range.

Maximum Ratings and Operating Conditions

Caution: Stressing the device beyond the absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and operation of the device beyond any specification or condition in the operating sections of this data sheet is not recommended. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 14: Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Units	Notes
T _{STG}	Storage temperature	–65	150	°C	
T _{LEAD}	Lead temperature during soldering	–	See note	°C	1
V _{IO}	Input and output voltage (with respect to ground)	–0.6	V _{CC} + 0.6	V	2
V _{CC}	Supply voltage	–0.6	4.0	V	
V _{ESD}	Electrostatic discharge voltage (Human Body model)	–2000	2000	V	3

- Notes:
1. The T_{LEAD} signal is compliant with JEDEC Std J-STD-020C (for small body, Sn-Pb or Pb assembly), the Micron RoHS-compliant 7191395 specification, and the European directive on Restrictions on Hazardous Substances (RoHS) 2002/95/EU.
 2. The minimum voltage may reach the value of –2V for no more than 20ns during transitions; the maximum may reach the value of V_{CC} +2V for no more than 20ns during transitions.
 3. The V_{ESD} signal: JEDEC Std JESD22-A114A (C1 = 100 pF, R1 = 1500Ω, R2 = 500Ω).

Table 15: Operating Conditions

Symbol	Parameter	Min	Typical	Max	Unit	Notes
V _{CC}	Supply voltage	2.3	–	3.6	V	1
T _A	Ambient operating temperature (grade 6)	–40	–	85	°C	2
T _A	Ambient operating temperature (grade 3)	–40	–	125	°C	3

- Notes:
1. Autograde 3 = 2.7V to 3.6V
 2. Autograde 6 and standard parts (grade 6) are tested to 85°C. Autograde 6 follows the high-reliability certified test flow.
 3. Autograde 3 is tested to 125°C.

Table 16: Data Retention and Endurance

Symbol	Condition	Min	Max	Unit
Program/Erase Cycles	Grade 6, grade 3, autograde 6	100,000	–	Cycles per block
Data Retention	at 55°C	20	–	Years

Electrical Characteristics

- Notes:
1. Applies to entire table: the AC specification values shown here are allowed only on the V_{CC} range 2.7V to 3.6V. The maximum frequency in the V_{CC} range 2.3V to 2.7V is 40 MHz.
 2. The t_{CH} and t_{CL} signal values must be greater than or equal to $1/f_C$.
 3. Typical values are given for $T_A = 25^\circ\text{C}$.
 4. The t_{CLCH} , t_{CHCL} , t_{SHQZ} , t_{HHQX} , t_{HLQZ} , t_{DP} , and t_{RDP} signal values are guaranteed by characterization, not 100% tested in production.
 5. The t_{CLCH} and t_{CHCL} signals clock rise and fall time values are expressed as a slew rate.
 6. The t_{WHSL} and t_{SHWL} signal values are only applicable as a constraint for a WRITE STATUS REGISTER command when SRWD bit is set at 1.

Table 22: AC Specifications 50 MHz

Symbol	Alt.	Parameter	Min	Typ	Max	Unit	Notes
f_C	f_C	Clock frequency for all commands (except READ)	D.C.	–	50	MHz	
f_R	–	Clock frequency for READ command	D.C.	–	25	MHz	
t_{CH}	t_{CLH}	Clock HIGH time	9	–	–	ns	2
t_{CL}	t_{CLL}	Clock LOW time	9	–	–	ns	2, 3
t_{CLCH}	–	Clock rise time (peak to peak)	0.1	–	–	V/ns	4, 5
t_{CHCL}	–	Clock fall time (peak to peak)	0.1	–	–	V/ns	4, 5
t_{SLCH}	t_{CSS}	S# active setup time (relative to C)	5	–	–	ns	
t_{CHSL}		S# not active hold time (relative to C)	5	–	–	ns	
t_{DVCH}	t_{DSU}	Data In setup time	2	–	–	ns	
t_{CHDX}	t_{DH}	Data In hold time	5	–	–	ns	
t_{CHSH}	–	S# active hold time (relative to C)	5	–	–	ns	
t_{SHCH}	–	S# not active setup time (relative to C)	5	–	–	ns	
t_{SHSL}	t_{CSH}	S# deselect time	100	–	–	ns	
t_{SHQZ}	t_{DIS}	Output disable time	–	–	8	ns	4
t_{CLQV}	t_V	Clock LOW to output valid	–	–	8	ns	
t_{CLQX}	t_{HO}	Output hold time	0	–	–	ns	
t_{HLCH}	–	HOLD# setup time (relative to C)	5	–	–	ns	
t_{CHHH}	–	HOLD# hold time (relative to C)	5	–	–	ns	
t_{HHCH}	–	HOLD# setup time (relative to C)	5	–	–	ns	
t_{CHHL}	–	HOLD# hold time (relative to C)	5	–	–	ns	
t_{HHQX}	t_{LZ}	HOLD# to output LOW-Z	–	–	8	ns	4
t_{HLQZ}	t_{HZ}	HOLD# to output HIGH-Z	–	–	8	ns	4
t_{WHSL}	–	WRITE PROTECT setup time	20	–	–	ns	6
t_{SHWL}	–	WRITE PROTECT hold time	100	–	–	ns	6
t_{DP}	–	S# HIGH to DEEP POWER-DOWN mode	–	–	3	μ s	4
t_{RES1}	–	S# HIGH to STANDBY without READ ELECTRONIC SIGNATURE	–	–	30	μ s	4
t_{RES2}	–	S# HIGH to STANDBY with READ ELECTRONIC SIGNATURE	–	–	30	μ s	4

- Notes:
1. Applies to entire table: the AC specification values shown here are allowed only on the V_{CC} range 2.7V to 3.6V. The maximum frequency in the V_{CC} range 2.3V to 2.7V is 40 MHz.
 2. The t_{CH} and t_{CL} signal values must be greater than or equal to $1/f_C$.
 3. Typical values are given for $T_A = 25^\circ\text{C}$.
 4. The t_{CLCH} , t_{CHCL} , t_{SHQZ} , t_{HHQX} , t_{HLQZ} , t_{DP} , and t_{RDP} signal values are guaranteed by characterization, not 100% tested in production.
 5. The t_{CLCH} and t_{CHCL} signals clock rise and fall time values are expressed as a slew rate.
 6. The t_{WHSL} and t_{SHWL} signal values are only applicable as a constraint for a WRITE STATUS REGISTER command when SRWD bit is set at 1.

Table 23: Instruction Times

Symbol	Parameter	Min	Typ	Max	Units	Notes
t_W	WRITE STATUS REGISTER cycle time	–	5	15	ms	
t_{PP}	PAGE PROGRAM cycle time (256 bytes)	–	1.4	5	ms	#electrical_specs/ note_42209 A42217A46 8FAC931C0F FFB51B80
t_{PP}	PAGE PROGRAM cycle time (n bytes)	–	See note			
t_{SE}	SECTOR ERASE cycle time	–	0.65	3	s	
t_{BE}	BULK ERASE cycle time	–	1.7	6	s	

- Notes:
1. When using the PAGE PROGRAM command to program consecutive bytes, optimized timings are obtained in one sequence that includes all the bytes rather than in several sequences of only a few bytes ($1 \leq n \leq 256$).
 2. $4\mu s + 8\mu s * [\text{int}(n-1)/2+1] + 4\mu s * [\text{int}(n-1)/2]$.

Device Ordering Information

Standard Parts

Micron Serial NOR Flash devices are available in different configurations and densities. Valid part numbers are at Micron's part catalog (www.micron.com), and feature and specification comparisons are at www.micron.com/products. Contact your sales representative for devices not found.

For more information on how to identify products and top side marking by the process identification letter, refer to technical note, TN-12-24: Serial Flash Memory Device Marking for the M25P, M25PE, M45PE, M25PX, and N25Q Product Families.

Micron recommends the use of the automotive grade device in the automotive environment, autograde 6 and grade 3. The high reliability certified flow (HRCF) is described in the quality note QNEE9801. Ask your Micron sales office for a copy. For further information on line items not listed here or on any aspect of this device, contact your nearest representative.

Table 24: Part Number Information Scheme

Part Number Category	Category Details	Notes
Device type	M25P = Serial Flash memory for code storage	
Density	10-A = 1Mb (128Kb x 8)	
Operating voltage	V = V _{CC} = 2.3V to 3.6V	
Package	MN = SO8N (150 mils width)	
	MP = VFQFPN8 6mm x 5mm (MLP8)	
Device Grade	6 = Industrial temperature range: -40°C to 85°C. Device tested with standard test flow.	1
Packing Option	- = Standard packing	
	T = Tape and reel packing	
Plating technology	P or G = RoHS-compliant	
Lithography	/Y TY redesigned	1

Note: 1. Exposed pad of 3mm x 3mm.

Note: The category of second Level Interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label.

Automotive Parts

Table 25: Part Number Information Scheme

Part Number Category	Category Details	Notes
Device type	M25P = Serial Flash memory for code storage	
Density	10-A = 1Mb (128Kb x 8)	
Operating voltage	V = V _{CC} = 2.7V to 3.6V	
Package	MN = SO8N (150 mils width)	
	MB = UFDFN8 (2mm x 3mm)	
Device Grade	6 = Industrial temperature range: –40°C to 85°C. Device tested with high reliability test flow.	
	3 = Automotive temperature range: –40°C to 125°C. Device tested with high reliability test flow.	1
Packing Option	– = Standard packing	
	T = Tape and reel packing	
Plating technology	P or G = RoHS-compliant	2
Lithography	Y = T7Y, 150nm technology (option available only with Device Grade Option = 6)	
	/Y = T7Y, 150nm technology (option available only with Device Grade Option = 3) Fab 13 diffusion plant	
Automotive Grade	A = Automotive: –40°C to 85°C part. Only with temperature grade 6. Device tested with high reliability test flow.	1
	– = Automotive: –40°C to 125°C.	

- Notes:
1. Micron recommends the use of the automotive grade device in the automotive environment, autograde 6 and grade 3.
 2. Contact your Micron sales representative for available options.

Revision History

Rev. C – 05/18

- Added Important Notes and Warnings section for further clarification aligning to industry standards

Rev. B – 05/14

- Replaced SO8W package with SO8N package.

Rev. A – 05/13

- Initial Micron rebrand.
