[1] Overvoltage at IN, S, or D is clamped by internal diodes. Current should be limited to the maximum ratings given.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

APPLICATIONS INFORMATION

ADG333A SUPPLY VOLTAGES

The ADG333A can operate from a dual or signal supply. V_{SS} should be connected to GND when operating with a single supply. When using a dual supply, the ADG333A can also operate with unbalanced supplies; for example V_{DD} = 20 V and V_{SS} = −5 V. The only restrictions are that V_{DD} to GND must not exceed 30 V, V_{SS} to GND must not drop below −30 V, and V_{DD} to V_{SS} must not exceed +44 V. It is important to remember that the ADG333A supply voltage directly affects the input signal range, the switch on resistance and the switching times of the device. The effects of the power supplies on these characteristics can be clearly seen from the Typical Performance Characteristics curves.

POWER SUPPLY SEQUENCING

When using CMOS devices, care must be taken to ensure correct power-supply sequencing. Incorrect power-supply sequencing can result in the device being subjected to stresses beyond those listed in the Absolute Maximum Ratings. This is also true for the ADG333A. Always turn on V_{DD} first, followed by V_{SS} and the logic signals. An external signal within the maximum specified ratings can then be safely presented to the source or drain of the switch.
