**Note 1:** Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

**Note 2:** The LTC1872E is guaranteed to meet performance specifications from 0°C to 70°C. Specifications over the –40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:**  $T_J$  is calculated from the ambient temperature  $T_A$  and power dissipation  $P_D$  according to the following formula:

$$T_J = T_A + (P_D \cdot \theta_{JA})^\circ\text{C/W}$$

**Note 4:** Dynamic supply current is higher due to the gate charge being delivered at the switching frequency.

**Note 5:** The LTC1872 is tested in a feedback loop that serves  $V_{FB}$  to the output of the error amplifier.

**Note 6:** Guaranteed by design at duty cycle = 30%. Peak current sense voltage is  $V_{REF}/6.67$  at duty cycle <40%, and decreases as duty cycle increases due to slope compensation as shown in Figure 2.

## PIN FUNCTIONS

**I<sub>TH</sub>/RUN (Pin 1):** This pin performs two functions. It serves as the error amplifier compensation point as well as the run control input. Nominal voltage range for this pin is 0.7V to 1.9V. Forcing this pin below 0.35V causes the device to be shut down. In shutdown all functions are disabled and the NGATE pin is held low.

**GND (Pin 2):** Ground Pin.

**V<sub>FB</sub> (Pin 3):** Receives the feedback voltage from an external resistive divider across the output.

**SENSE<sup>-</sup> (Pin 4):** The Negative Input to the Current Comparator.

**V<sub>IN</sub> (Pin 5):** Supply Pin. Must be closely decoupled to GND Pin 2.

**NGATE (Pin 6):** Gate Drive for the External N-Channel MOSFET. This pin swings from 0V to V<sub>IN</sub>.

## FUNCTIONAL DIAGRAM

## OPERATION (Refer to Functional Diagram)

## Main Control Loop

The LTC1872 is a constant frequency current mode switching regulator. During normal operation, the external N-channel power MOSFET is turned on each cycle by the oscillator and turned off when the current comparator (ICMP) resets the RS latch. The peak inductor current at which ICMP resets the RS latch is controlled by the voltage on the  $I_{TH}/RUN$  pin, which is the output of the error amplifier EAMP. An external resistive divider connected between  $V_{OUT}$  and ground allows the EAMP to receive an output feedback voltage  $V_{FB}$ . When the load current increases, it causes a slight decrease in  $V_{FB}$

relative to the 0.8V reference, which in turn causes the  $I_{TH}/RUN$  voltage to increase until the average inductor current matches the new load current.

The main control loop is shut down by pulling the  $I_{TH}/RUN$  pin low. Releasing  $I_{TH}/RUN$  allows an internal  $0.5\mu A$  current source to charge up the external compensation network. When the  $I_{TH}/RUN$  pin reaches 0.35V, the main control loop is enabled with the  $I_{TH}/RUN$  voltage then pulled up to its zero current level of approximately 0.7V. As the external compensation network continues to charge up, the corresponding output current trip level follows, allowing normal operation.

## OPERATION

Comparator OVP guards against transient overshoots >7.5% by turning off the external N-channel power MOSFET and keeping it off until the fault is removed.

### Burst Mode Operation

The LTC1872 enters Burst Mode operation at low load currents. In this mode, the peak current of the inductor is set as if  $V_{I_{TH}/RUN} = 1V$  (at low duty cycles) even though the voltage at the  $I_{TH}/RUN$  pin is at a lower value. If the inductor's average current is greater than the load requirement, the voltage at the  $I_{TH}/RUN$  pin will drop. When the  $I_{TH}/RUN$  voltage goes below 0.85V, the sleep signal goes high, turning off the external MOSFET. The sleep signal goes low when the  $I_{TH}/RUN$  voltage goes above 0.925V and the LTC1872 resumes normal operation. The next oscillator cycle will turn the external MOSFET on and the switching cycle repeats.

### Undervoltage Lockout

To prevent operation of the N-channel MOSFET below safe input voltage levels, an undervoltage lockout is incorporated into the LTC1872. When the input supply voltage drops below approximately 2.0V, the N-channel MOSFET and all circuitry is turned off except the undervoltage block, which draws only several microamperes.

### Overvoltage Protection

The overvoltage comparator in the LTC1872 will turn the external MOSFET off when the feedback voltage has risen 7.5% above the reference voltage of 0.8V. This comparator has a typical hysteresis of 20mV.

### Slope Compensation and Inductor's Peak Current

The inductor's peak current is determined by:

$$I_{PK} = \frac{V_{I_{TH}} - 0.7}{10(R_{SENSE})}$$

when the LTC1872 is operating below 40% duty cycle. However, once the duty cycle exceeds 40%, slope compensation begins and effectively reduces the peak inductor current. The amount of reduction is given by the curves in Figure 2.

### Short-Circuit Protection

Since the power switch in a boost converter is not in series with the power path from input to load, turning off the switch provides no protection from a short-circuit at the output. External means such as a fuse in series with the boost inductor must be employed to handle this fault condition.

Figure 2. Maximum Output Current vs Duty Cycle

## APPLICATIONS INFORMATION

The basic LTC1872 application circuit is shown in Figure 1. External component selection is driven by the load requirement and begins with the selection of L1 and R<sub>SENSE</sub> (= R1). Next, the power MOSFET and the output diode D1 is selected followed by C<sub>IN</sub>(= C1) and C<sub>OUT</sub>(= C2).

### R<sub>SENSE</sub> Selection for Output Current

R<sub>SENSE</sub> is chosen based on the required output current. With the current comparator monitoring the voltage developed across R<sub>SENSE</sub>, the threshold of the comparator determines the inductor's peak current. The output current the LTC1872 can provide is given by:

$$I_{OUT} = \left( \frac{0.12}{R_{SENSE}} - \frac{I_{RIPPLE}}{2} \right) \frac{V_{IN}}{V_{OUT} + V_D}$$

where I<sub>RIPPLE</sub> is the inductor peak-to-peak ripple current (see Inductor Value Calculation section) and V<sub>D</sub> is the forward drop of the output diode at the full rated output current.

A reasonable starting point for setting ripple current is:

$$I_{RIPPLE} = (0.4)(I_{OUT}) \frac{V_{OUT} + V_D}{V_{IN}}$$

Rearranging the above equation, it becomes:

$$R_{SENSE} = \frac{1}{(10)(I_{OUT})} \left( \frac{V_{IN}}{V_{OUT} + V_D} \right)$$

for Duty Cycle <40%

However, for operation that is above 40% duty cycle, slope compensation's effect has to be taken into consideration to select the appropriate value to provide the required amount of current. Using the scaling factor (SF, in %) in Figure 2, the value of R<sub>SENSE</sub> is:

$$R_{SENSE} = \frac{SF}{(10)(I_{OUT})(100)} \left( \frac{V_{IN}}{V_{OUT} + V_D} \right)$$

### Inductor Value Calculation

The operating frequency and inductor selection are inter-related in that higher operating frequencies permit the use of a smaller inductor for the same amount of inductor ripple current. However, this is at the expense of efficiency due to an increase in MOSFET gate charge losses.

The inductance value also has a direct effect on ripple current. The ripple current, I<sub>RIPPLE</sub>, decreases with higher inductance or frequency and increases with higher V<sub>OUT</sub>. The inductor's peak-to-peak ripple current is given by:

$$I_{RIPPLE} = \frac{V_{IN}}{f(L)} \left( \frac{V_{OUT} + V_D - V_{IN}}{V_{OUT} + V_D} \right)$$

where f is the operating frequency. Accepting larger values of I<sub>RIPPLE</sub> allows the use of low inductances, but results in higher output voltage ripple and greater core losses. A reasonable starting point for setting ripple current is:

$$I_{RIPPLE} = 0.4(I_{OUT(MAX)}) \left( \frac{V_{OUT} + V_D}{V_{IN}} \right)$$

In Burst Mode operation, the ripple current is normally set such that the inductor current is continuous during the burst periods. Therefore, the peak-to-peak ripple current must not exceed:

$$I_{RIPPLE} \leq \frac{0.03}{R_{SENSE}}$$

This implies a minimum inductance of:

$$L_{MIN} = \frac{V_{IN}}{f \left( \frac{0.03}{R_{SENSE}} \right)} \left( \frac{V_{OUT} + V_D - V_{IN}}{V_{OUT} + V_D} \right)$$

A smaller value than L<sub>MIN</sub> could be used in the circuit; however, the inductor current will not be continuous during burst periods.

## APPLICATIONS INFORMATION

### Inductor Selection

When selecting the inductor, keep in mind that inductor saturation current has to be greater than the current limit set by the current sense resistor. Also, keep in mind that the DC resistance of the inductor will affect the efficiency. Off the shelf inductors are available from Murata, Coilcraft, Toko, Panasonic, Coiltronics and many other suppliers.

### Power MOSFET Selection

The main selection criteria for the power MOSFET are the threshold voltage  $V_{GS(TH)}$ , the “on” resistance  $R_{DS(ON)}$ , reverse transfer capacitance  $C_{RSS}$  and total gate charge.

Since the LTC1872 is designed for operation down to low input voltages, a logic level threshold MOSFET ( $R_{DS(ON)}$  guaranteed at  $V_{GS} = 2.5V$ ) is required for applications that work close to this voltage. When these MOSFETs are used, make sure that the input supply to the LTC1872 is less than the absolute maximum  $V_{GS}$  rating, typically 8V.

The required minimum  $R_{DS(ON)}$  of the MOSFET is governed by its allowable power dissipation given by:

$$R_{DS(ON)} \cong \frac{P_P}{(DC) I_{IN}^2 (1 + \delta p)}$$

where  $P_P$  is the allowable power dissipation and  $\delta p$  is the temperature dependency of  $R_{DS(ON)}$ .  $(1 + \delta p)$  is generally given for a MOSFET in the form of a normalized  $R_{DS(ON)}$  vs temperature curve, but  $\delta p = 0.005/^\circ C$  can be used as an approximation for low voltage MOSFETs. DC is the maximum operating duty cycle of the LTC1872.

### Output Diode Selection

Under normal load conditions, the average current conducted by the diode in a boost converter is equal to the output load current:

$$I_{D(avg)} = I_{OUT}$$

It is important to adequately specify the diode peak current and average power dissipation so as not to exceed the diode ratings.

Schottky diodes are recommended for low forward drop and fast switching times. Remember to keep lead length short and observe proper grounding (see Board Layout Checklist) to avoid ringing and increased dissipation.

### $C_{IN}$ and $C_{OUT}$ Selection

To prevent large input voltage ripple, a low ESR input capacitor sized for the maximum RMS current must be used. The maximum RMS capacitor current for a boost converter is approximately equal to:

$$C_{IN} \text{ Required } I_{RMS} \approx (0.3) I_{RIPPLE}$$

where  $I_{RIPPLE}$  is as defined in the Inductor Value Calculation section.

Note that capacitor manufacturer's ripple current ratings are often based on 2000 hours of life. This makes it advisable to further derate the capacitor, or to choose a capacitor rated at a higher temperature than required. Several capacitors may be paralleled to meet the size or height requirements in the design. Due to the high operating frequency of the LTC1872, ceramic capacitors can also be used for  $C_{IN}$ . Always consult the manufacturer if there is any question.

The selection of  $C_{OUT}$  is driven by the required effective series resistance (ESR). Typically, once the ESR requirement is satisfied, the capacitance is adequate for filtering. The output ripple ( $\Delta V_{OUT}$ ) is approximated by:

$$\Delta V_{OUT} \approx \left( I_O \cdot \frac{V_{OUT} + V_D}{V_{IN}} + \frac{I_{RIPPLE}}{2} \right) \cdot \left[ ESR^2 + \left( \frac{1}{2\pi f C_{OUT}} \right)^2 \right]^{\frac{1}{2}}$$

## APPLICATIONS INFORMATION

where  $f$  is the operating frequency,  $C_{OUT}$  is the output capacitance and  $I_{RIPPLE}$  is the ripple current in the inductor.

Manufacturers such as Nichicon, United Chemicon and Sanyo should be considered for high performance through-hole capacitors. The OS-CON semiconductor dielectric capacitor available from Sanyo has the lowest ESR (size) product of any aluminum electrolytic at a somewhat higher price. The output capacitor RMS current is approximately equal to:

$$I_{PK} \cdot \sqrt{DC - DC^2}$$

where  $I_{PK}$  is the peak inductor current and  $DC$  is the switch duty cycle.

When using electrolytic output capacitors, if the ripple and ESR requirements are met, there is likely to be far more capacitance than required.

In surface mount applications, multiple capacitors may have to be paralleled to meet the ESR or RMS current handling requirements of the application. Aluminum electrolytic and dry tantalum capacitors are both available in surface mount configurations. An excellent choice of tantalum capacitors is the AVX TPS and KEMET T510 series of surface mount tantalum capacitors. Also, ceramic capacitors in X5R or X7R dielectrics offer excellent performance.

### Low Supply Operation

Although the LTC1872 can function down to approximately 2.0V, the maximum allowable output current is reduced when  $V_{IN}$  decreases below 3V. Figure 3 shows the amount of change as the supply is reduced down to 2V. Also shown in Figure 3 is the effect of  $V_{IN}$  on  $V_{REF}$  as  $V_{IN}$  goes below 2.3V.

### Setting Output Voltage

The LTC1872 develops a 0.8V reference voltage between the feedback (Pin 3) terminal and ground (see Figure 4). By selecting resistor  $R1$ , a constant current is caused to flow through  $R1$  and  $R2$  to set the overall output voltage. The regulated output voltage is determined by:

$$V_{OUT} = 0.8V \left( 1 + \frac{R2}{R1} \right)$$

Figure 3. Line Regulation of  $V_{REF}$  and  $V_{ITH}$

Figure 4. Setting Output Voltage

## APPLICATIONS INFORMATION

For most applications, an 80k resistor is suggested for R1. To prevent stray pickup, locate resistors R1 and R2 close to LTC1872.

### Efficiency Considerations

The efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Efficiency can be expressed as:

$$\text{Efficiency} = 100\% - (\eta_1 + \eta_2 + \eta_3 + \dots)$$

where  $\eta_1$ ,  $\eta_2$ , etc. are the individual losses as a percentage of input power.

Although all dissipative elements in the circuit produce losses, four main sources usually account for most of the losses in LTC1872 circuits: 1) LTC1872 DC bias current, 2) MOSFET gate charge current, 3)  $I^2R$  losses and 4) voltage drop of the output diode.

1. The  $V_{IN}$  current is the DC supply current, given in the electrical characteristics, that excludes MOSFET driver and control currents.  $V_{IN}$  current results in a small loss which increases with  $V_{IN}$ .

2. MOSFET gate charge current results from switching the gate capacitance of the power MOSFET. Each time a MOSFET gate is switched from low to high to low again, a packet of charge,  $dQ$ , moves from  $V_{IN}$  to ground. The resulting  $dQ/dt$  is a current out of  $V_{IN}$  which is typically much larger than the controller's DC supply current. In continuous mode,  $I_{GATECHG} = f(Q_p)$ .
3.  $I^2R$  losses are predicted from the DC resistances of the MOSFET, inductor and current sense resistor. The MOSFET  $R_{DS(ON)}$  multiplied by duty cycle times the average output current squared can be summed with  $I^2R$  losses in the inductor ESR in series with the current sense resistor.
4. The output diode is a major source of power loss at high currents. The diode loss is calculated by multiplying the forward voltage by the load current.
5. Transition losses apply to the external MOSFET and increase at higher operating frequencies and input voltages. Transition losses can be estimated from:

$$\text{Transition Loss} = 2(V_{IN})^2 I_{IN(MAX)} C_{RSS}(f)$$

Other losses, including  $C_{IN}$  and  $C_{OUT}$  ESR dissipative losses, and inductor core losses, generally account for less than 2% total additional loss.

## APPLICATIONS INFORMATION

### PC Board Layout Checklist

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the LTC1872. These items are illustrated graphically in the layout diagram in Figure 5. Check the following in your layout:

1. The Schottky diode should be closely connected between the output capacitor and the drain of the external MOSFET.
2. The (+) plate of  $C_{IN}$  should connect to the sense resistor as closely as possible. This capacitor provides AC current to the inductor.
3. The input decoupling capacitor ( $0.1\mu\text{F}$ ) should be connected closely between  $V_{IN}$  (Pin 5) and ground (Pin 2).
4. Connect the end of  $R_{SENSE}$  as close to  $V_{IN}$  (Pin 5) as possible. The  $V_{IN}$  pin is the  $\text{SENSE}^+$  of the current comparator.
5. The trace from  $\text{SENSE}^-$  (Pin 4) to the Sense resistor should be kept short. The trace should connect close to  $R_{SENSE}$ .
6. Keep the switching node  $\text{NGATE}$  away from sensitive small signal nodes.
7. The  $V_{FB}$  pin should connect directly to the feedback resistors. The resistive divider  $R1$  and  $R2$  must be connected between the (+) plate of  $C_{OUT}$  and signal ground.

| <a href="#">LT1680</a>          | High Power DC/DC Step-Up Controller                           | Operation Up to 60V, Fixed Frequency Current Mode            |
| <a href="#">LTC1624</a>         | High Efficiency SO-8 N-Channel Switching Regulator Controller | 8-Pin N-Channel Drive, $3.5V \leq V_{IN} \leq 36V$           |
| <a href="#">LT1615</a>          | Micropower Step-Up DC/DC Converter in SOT-23                  | 20µA Quiescent Current, $V_{IN}$ Down to 1V                  |
| <a href="#">LTC1700</a>         | No RSENSE Synchronous Current Mode DC/DC Step-Up Controller   | 95% Efficient, $0.9V \leq V_{IN} \leq 5V$ , 550kHz Operation |
| <a href="#">LTC1772</a>         | Constant Frequency Current Mode Step-Down DC/DC Controller    | $V_{IN}$ 2.5V to 9.8V, $I_{OUT}$ up to 4A, SOT-23 Package    |
| <a href="#">LTC3401/LTC3402</a> | 1A/2A, 3MHz Micropower Synchronous Boost Converter            | 10-Lead MSOP Package, $0.5V \leq V_{IN} \leq 5V$             |
