

## ABSOLUTE MAXIMUM RATINGS

$V_{IN}$ ,  $V_{MODE}$ ,  $V_{OUT}$  and EN/PWM ..... -0.3V to 6V  
 Output Current ( $I_{OUT}$ ) ..... 300mA  
 Power Dissipation per Package - 10-pin DFN  
 (derate 8.84mW/°C above +70°C) ..... 1.2W  
 Junction Temperature ..... +125°C  
 Storage Temperature ..... -65°C to +150°C  
 ESD Rating ..... 2kV HBM

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

## ELECTRICAL CHARACTERISTICS

Unless otherwise specified:  $V_{IN} = 3.6V$ ,  $C1 = C4 = 2.2\mu F$  &  $C2 = C3 = 1\mu F$  (Ceramic, ESR=0.03Ω) and  $T_{AMB} = 25^\circ$ .

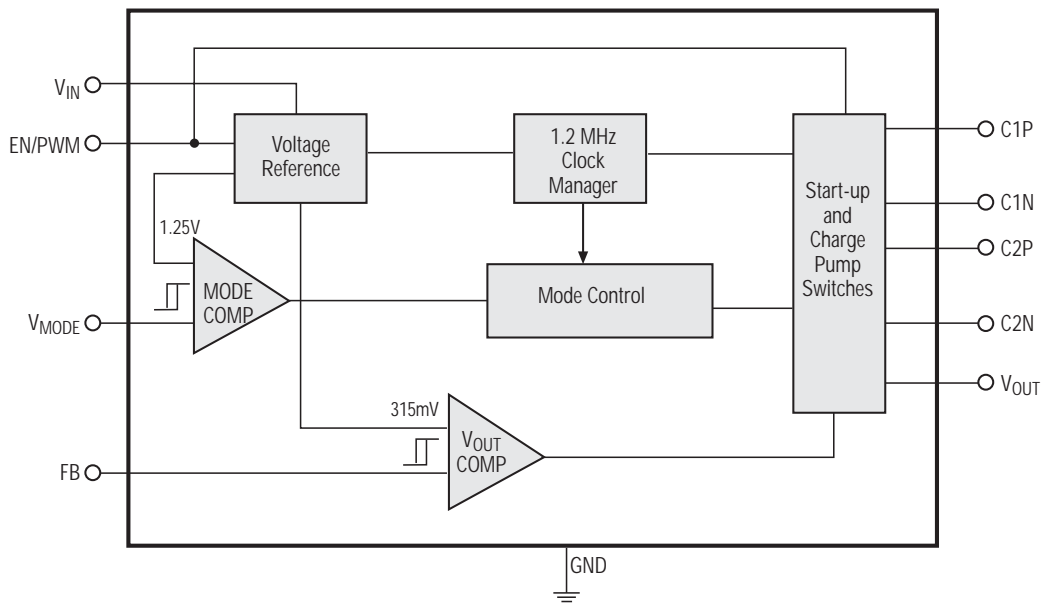

The ♦ denotes specifications which apply over full operating temperature range -40°C to +85°C.

Parameter	Min.	Typ.	Max.	Units		Conditions
Input Voltage	2.7		5.5	V	♦	
Quiescent Current		0.5	3	mA	♦	$V_{IN} = 3.0 - 5.5V$ , $V_{OUT} = 3.6V$ , $I_{OUT} = 100\mu A$
Shutdown Current		0.5	1.5	$\mu A$	♦	$V_{EN}/PWM = 0.0V$ , $V_{IN} = 5.5V$
Maximum Load Current		200		mA		$V_{IN} = 4.2V$ , $V_{OUT} = 3.6V$

## PIN DESCRIPTION

PIN NUMBER	PIN NAME	DESCRIPTION
1	$V_{OUT}$	Regulated charge pump output.
2	C1P	Positive terminal to the charge pump flying capacitor C2.
3	$V_{IN}$	Input supply voltage.
4	$V_{MODE}$	Charge pump mode program pin. When $V_{MODE}$ is greater than 1.25V, a X1 charge pump is used. Otherwise, charge pump switches to X1.5 mode. A voltage divider shown in the typical application circuit programs the $V_{IN}$ threshold for charge pump mode switching.
5	FB	This is the feedback pin for output current or voltage regulation. The voltage of this pin is compared with an internal 315mV reference.
6	EN/PWM	Enable and PWM dimming control input. Pull this pin low to disconnect $V_{OUT}$ from $V_{IN}$ and shutdown the SP6683. $V_{OUT}$ is pulled to ground in shutdown.
7	C2N	Negative terminal to the charge pump flying capacitor, C4.
8	GND	Ground reference.
9	C1N	Negative terminal to the charge pump flying capacitor, C2.
10	C2P	Positive terminal to the charge pump flying capacitor C4.

## FUNCTIONAL DIAGRAM

# TYPICAL PERFORMANCE CHARACTERISTICS (25°C)

## General Overview

The SP6683 is a current regulated charge pump ideal for converting a Li-Ion battery input for driving white LEDs used in camera flash or backlighting color displays in cellular phones, PDAs, digital cameras and MP3 players. The SP6683 is able to efficiently drive one 200mA Flash LED or up to eight 20mA white LEDs in parallel and maintain a constant brightness over a very wide operating voltage range (2.7V to 5.5V). The SP6683 operates with an internal 1.2MHz clock, enabling the use of small external components. Other features of SP6683 include PWM dimming control as well as complete input/output disconnect in shutdown. In shutdown mode the IC typically draws 500nA current. The output regulation is achieved by sensing the voltage at the feedback pin and modulating the switch between the charge pump and output capacitor.

## Theory of Operation

The SP6683 regulated charge pump block diagram consists of four main blocks (Voltage Reference, Mode Control, Clock Manager, Start-up and Charge-Pump Switches) and two comparators ( $V_{MODE}$  Comparator and  $V_{OUT}$  Comparator).

**1) Voltage Reference.** This block provides the 315mV and 1.25V reference voltages needed for the two comparators.

**2) Mode Control.** An external voltage divider connected to the  $V_{MODE}$  pin will define an input voltage to the mode comparator which sets the logic state of the mode selection outputs to the X1 or X1.5 modes.  $V_{MODE}$  is compared to a 1.25V bandgap voltage. For example, if one makes a 158K/100K divider, the mode will change at  $2.58 \times 1.25 \text{ V} = 3.23 \text{ V}$ . A comparator-based cycle by cycle regulation ensures that no mode change occurs during cycles.

**3) Clock Manager.** An internal 1.2MHz clock is generated in this block. Depending on the mode control, the appropriate clock phasing is generated here and sent to the startup and charge pump switches block.

**4)  $V_{OUT}$  Comparator & Output Control.** A 315mV reference voltage is compared to feedback voltage to control the  $V_{OUT}$  needed for the application. Output current is set by a bias resistor from the FB pin to the GND pin chosen by the relationship:

$$I_{OUT} = \frac{V_{FB}}{R_{FB}}$$

where  $V_{FB} = 315 \text{ mV}$ .

## Configuring the SP6683 as Voltage or Current Source

The white LED load configuration used by customers can be discrete white LEDs or a white LED module. Inside the white LED module, there may or may not be resistors in series with the white LEDs. According to the different application requirements, the SP6683 can be configured as either a voltage source or a current source to provide solutions for these different applications, as shown below. The figure shows the SP6683 driving discrete white LEDs as a current source.

*Driving discrete white LEDs as current source*

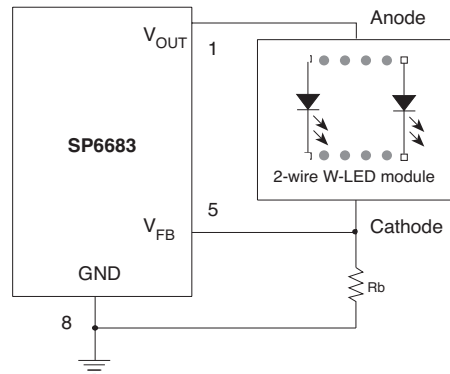

The current in one white LED current is set by the ratio of the feedback pin voltage (315mV) and the bias resistor  $R_B$ . To set the operating current,  $R_B$  can be selected by:

$$R_B = \frac{V_{FB}}{I_{LED}}$$

The current of the remaining white LEDs is set according to the similarity of the white LEDs. 3-wire white LED modules with internal series resistors (as shown in figure below) can also be driven in this way.

*3-wire white LED module*

*Driving 2-wire white LED module as current source*

In the figure above, the SP6683 was used to drive a 2-wire white LED module (without internal series resistors) as a current source. The bias resistor  $R_B$  is selected to regulate the total current of the white LED module instead of the current of a single LED as in the figure showing the 3 wire white LED module.

*Driving 2-wire white LED module as voltage source*

In this application, the bias resistor can be selected by:

$$R_B = \frac{V_{FB}}{I_{LED(TOTAL)}}$$

where  $I_{LED(TOTAL)}$  is the total operating current of all the white LEDs.

To use SP6683 as a voltage source for fixed voltage applications, a voltage divider is need to program the output voltage, as shown in the figure above. The output voltage is set by the ratio of the two resistors and the feedback control voltage as shown by:

$$V_{OUT} = \left(1 + \frac{R_5}{R_6}\right) \cdot V_{FB}$$

### Brightness Control Using PWM

Dimming control can be achieved by applying a PWM control signal to the EN/PWM pin. The brightness of the white LEDs is controlled by increasing and decreasing the duty cycle of the PWM signal. While operating frequency range is from 60Hz to 700Hz, the recommended maximum brightness frequency range is from 60Hz to 200Hz. A repetition rate of at least 60Hz is required to prevent flicker.

### Three Options for Optimization

The SP6683 family includes three options that allow the user to optimize the LED driving circuit. The SP6683 includes an on-board discharge switch that ensures that  $V_{OUT}$  is completely discharged in shutdown. This feature is very useful in systems using PWM dimming, when the SP6683 is periodically turned on and off. The discharge switch ensures that the falling and rising edges of the LED current have similar durations.

The SP6683-03ER has the discharge MOSFET disabled ensuring that the output node is at high impedance during shutdown. This can be useful if the system is feeding LED current from another source while the SP6683 is in shutdown.

The SP6683-LV offers a lower reference voltage that allows to reduce efficiency loss occurring in the current sense resistor. This part is ideal for driving single LEDs for Flash applications.

### Reducing Component Count

It is possible to reduce the number of external components by shorting pins 2 & 9 and omitting the flying capacitor. In this mode, the charge pump operates in a "quasi" doubler mode. This reduces efficiency but does allow for one less external capacitor. This circuit is recommended only when Input and Output Voltages have similar range, which is very common when driving white LEDs from a Li-Io battery.

*Flying Cap Removed*

## Component Selection

The guideline for selecting divider resistors is as follows. For high input voltage, the SP6683 will work in X1 mode. When the input voltage drops to  $V_{TH}$  threshold voltage, it will switch to X1.5 mode automatically. The  $V_{TH}$  threshold voltage for mode change can be calculated by:

$$V_{TH} = (V_F + 0.315 + m \cdot I_{LED} \cdot R_{OUT})$$

Where  $V_F$  and  $m$  are the forward voltage and number of the white LEDs,  $R_{OUT}$  is the output resistance of the SP6683.

The equation for the voltage divider  $R_1$  and  $R_2$  with  $V_{MODE} = 1.25V$  is:

$$V_{TH} = 1.25V \cdot (1 + R_1/R_2)$$

Which can be expressed as  $R_1$ :

$$R_1 = [(V_{TH}/1.25) - 1] R_2$$

For the typical SP6683 application, using  $V_F = 3.6V$ ,  $m = 8$ ,  $I_{LED} = 15mA$ ,  $R_{OUT} = 6\Omega$ ,  $V_{TH}$  will be  $4.63V$ , Select  $R_2 = 100k\Omega$ , then  $R_1 = 270k\Omega$

Ceramic capacitors are recommended for their inherently low ESR, which will help produce low peak-to-peak output ripple, and reduce high frequency spikes.

The fly capacitor controls the strength of the charge pump. Selection of the fly capacitor is a tradeoff between the output voltage ripple and the output current capability. Decreasing the fly capacitor will reduce the output voltage ripple because less charge will be delivered to the output capacitor. However, a smaller fly capacitor leads to larger output resistance, thus decreasing the output current capability and the efficiency of the circuit. Increasing the value of the input and output capacitors could further reduce the input and output ripple. For back-lighting applications up to 80mA output current,  $C_{IN} = C_{OUT} = 1\mu F$  is typically used. For applications with more than 80mA output current, for example in Flash applications where  $I_{OUT}$  can be as much as 200mA,  $C_{IN} = C_{OUT} = 2.2\mu F$  is recommended. For peak performance, place all capacitors as close to the SP6683 as possible.

Refer to table 1 below for some suggested low ESR capacitors.

### SUGGESTED LOW ESR CAPACITORS

Manufacturers/ Website	Part Number	Capacitance/ Voltage	Capacitor Size/Type/Thickness	ESR at 100KHz

## Brightness Matching

For white LEDs, the forward voltage drop is a function of the operating current. However, for a given current, the forward voltage drop across each LED does not always match exactly. This can cause uneven brightness in the white LEDs.

In the figure below, assuming high-precision bias resistors were used, the operating current ratio of two different branches can be easily derived as shown by:

$$\frac{I_1}{I_2} = \frac{V_{OUT} - V_{F1}}{V_{OUT} - V_{F2}}$$

where  $I_1$  &  $I_2$  are the operating current of the white LEDs, where  $V_{F1}$  &  $V_{F2}$  are the forward voltage of the white LEDs.

Since the brightness of the white LED is proportional to the operating current, for better brightness matching, a higher output voltage could be

used. This could be done by using a larger resistor, as shown in the figure below. Rb2 is used to bias the operating current of the white LED, Rb1 is use to increase the output voltage. Better brightness matching was achieved at the cost of the power wasted on the bias resistor.

## Power Efficiency

The efficiency of driving the white LEDs can be calculated by

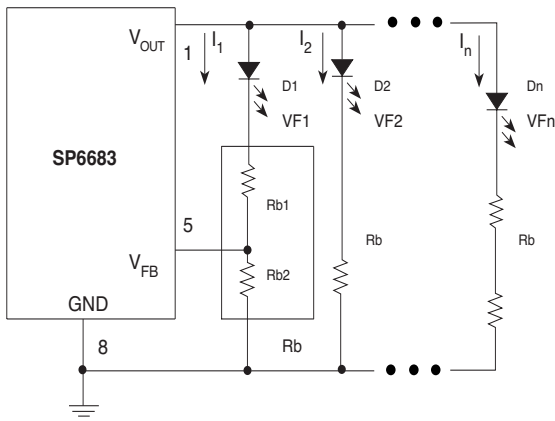

$$\eta = \frac{V_F \cdot I_F}{V_i \cdot I_i} = \frac{V_F \cdot I_F}{V_i \cdot (n \cdot I_F + I_Q)} \approx \frac{V_F}{V_i \cdot n}$$

Where

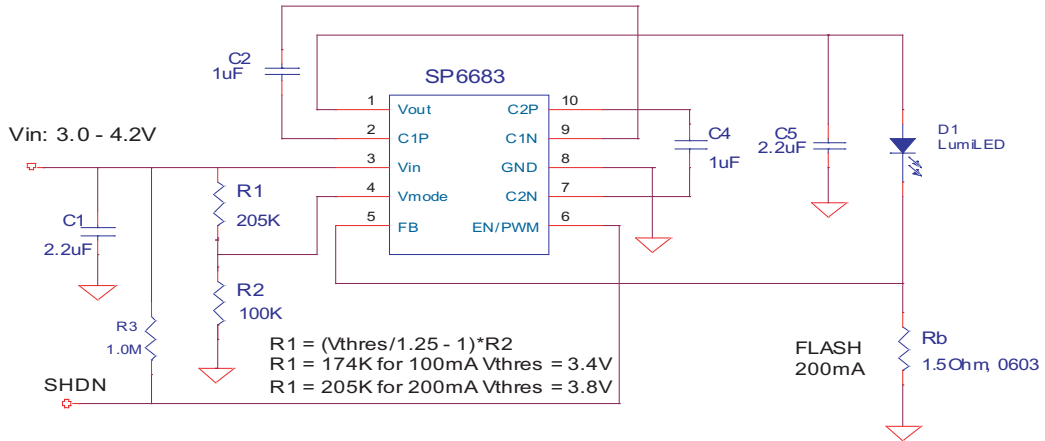

$V_i$  &  $I_i$  are input voltage and current;

$V_F$  &  $I_F$  are the forward voltage and operating current of the White LED;

$I_Q$  is quiescent current, which is considered small compared with  $I_F$ .

*Improving brightness matching*
