

The device has features that are programmable on a per-stream or a per-channel basis including message mode, input delay offset, output advancement offset, and direction control.

The ZL50031 supports all three of the H.110 specification required clocking modes: Primary Master, Secondary Master and Slave.

HQFP Pinout Diagram

Figure 1 - ZL50031 256-Pin 28 mm x 28 mm HQFP (top view)

Pin Description

256 Pin HQFP	Name	Description
8,18,37,49 62,70,78,89,95 101,107,113,120 135,145,156,164 172,180,198,204 212,220,231,243 253	V _{DD}	+3.3 Volt Power Supply.
155,187,197,229	V _{DD5V}	+5.0 V/+3.3 V Power Supply. If 5 V power supply is tied to these pins, BSTio0-31 pins will meet 5 V PCI requirements. If 3.3 V power supply is tied to these pins, BSTio0-31 pins will meet 3.3 V PCI requirements.
7,17,36,43,48 59,69,77,88,94 100,106,112,119 125,134,144 163,171,179,188 203,211,219,230 242,252	V _{SS}	Ground.
44	APLLV _{DD}	+3.3 Volt Analog PLL Power Supply. No special filtering is required for this pin.
45	APLLV _{SS}	Analog PLL Ground
19	$\overline{\text{RESET}}$	Device Reset (5 V Tolerant Input). This input (active low) puts the device in its reset state; this state clears the device's internal counters and registers. To ensure proper reset action, the reset pin must be low for longer than 400 ns. To ensure proper operation, a delay of 100 μ s must be <u>applied</u> before the first microprocessor access is performed after the $\overline{\text{RESET}}$ pin is set high. The device reset also tristates LSTio0-15 and BSTio0-31. When in a RESET condition, the C8_A_io, FRAME_A_io, C8_B_io, and FRAME_B_io signals are tri-stated.
226 to 223 218 to 215 210 to 207 202 to 199	BSTio0-3, BSTio4-7, BSTio8-11, BSTio12-15	Backplane Serial Input/Output Streams 0 - 15 (5 V Tolerant PCI I/Os). In H.110 mode, these pins accept or output (selectable on a per channel basis) serial TDM data streams at 8.192 Mbps with 128 channels per stream. In the 16 Mbps mode, these pins accept serial TDM data streams at 16.384 Mbps with 256 channels per stream respectively.
186 to 183 178 to 175 170 to 167 162 to 159	BSTio16-19, BSTio20-23, BSTio24-27, BSTio28-31	Backplane Serial Input/Output Streams 16 - 31 (5 V Tolerant PCI I/Os). In H.110 mode, these pins accept or output (selectable on a per channel basis) serial TDM data streams at 8.192 Mbps with 128 channels per stream. In the 16 Mbps mode, these pins are tristated internally and should be connected to ground.
153 to 150	LSTio - 3	Local Serial Input Streams 0 to 3 (5 V Tolerant Inputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these inputs accept data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
149 to 146	LSTi4 - 7	Local Serial Input Streams 4 to 7 (5 V Tolerant Inputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these inputs accept data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.

Pin Description (continued)

256 Pin HQFP	Name	Description
143 TO 140	LSTi8 - 11	Local Serial Input Streams 8 to 11 (5 V Tolerant Inputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these inputs accept data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
139 to 136	LSTi12 - 15	Local Serial Input Streams 12 to 15 (5 V Tolerant Inputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these inputs accept data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
117 to 114	LSTo0 - 3	Local Serial Output Streams 0 to 3 (5 V Tolerant Tri-state Outputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these outputs have data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
111 to 108	LSTo4 - 7	Local Serial Output Streams 4 to 7 (5 V Tolerant Tri-state Outputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these outputs have data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
105 to 102	LSTo8 - 11	Local Serial Output Streams 8 to 11 (5 V Tolerant Tri-state Outputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these outputs have data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
99 to 96	LSTo12 - 15	Local Serial Output Streams 12 to 15 (5 V Tolerant Tri-state Outputs): In 2 Mb/s, 4 Mb/s or 8 Mb/s mode, these outputs have data rates of 2.048 Mb/s, 4.096 Mb/s or 8.192 Mb/s with 32, 64 or 128 channels per stream respectively.
79	ODE	Output Drive Enable (5 V Tolerant Input). When this pin is low, LSTo0-15, BSTio0-31, C1M5o, C32/64o, ST_CKo0, ST_CKo1, ST_FPo0 and ST_FPo1 outputs are all in high-impedance state. When ODE is high all of the aforementioned pins are active.
46	C20i	Master Clock (5 V Tolerant Input). This pin accepts a 20.000 MHz clock.
76	C8_A_io	Clock A (5 V Tolerant I/O). This is an 8.192 MHz clock with 50% duty cycle.
75	FRAME_A_io	Frame Reference A (5 V Tolerant I/O). This is a 122 ns wide, negative pulse, with 125 μ s period.
73	C8_B_io	Clock B (5 V Tolerant I/O). This is an 8.192 MHz clock with 50% duty cycle.
72	FRAME_B_io	Frame Reference B (5 V Tolerant I/O). This is a 122 ns wide, negative pulse, with 125 μ s period.
74	FAIL_A	A Failure (Output). When the C8_A_io or the FRAME_A_io signal fails, this signal goes to high.
71	FAIL_B	B Failure (Output). When the C8_B_io or the FRAME_B_io signal fails, this signal goes to high.
68	CTREF1	CT-Bus Reference 1 (5 V Tolerant Input). This pin accepts 8 kHz, 1.544 MHz or 2.048 MHz network timing reference.
67	CTREF2	CT-Bus Reference 2 (5 V Tolerant Input). This pin accepts 8 kHz, 1.544 MHz or 2.048 MHz network timing reference.

Pin Description (continued)

256 Pin HQFP	Name	Description
57 to 54	LREF0 - 3	Local Reference (5 V Tolerant Inputs). These pins accept 8 kHz, 1.544 MHz or 2.048 MHz local timing reference.
66	NREFo	Network Reference Output (Output). Any local reference can be switched to this output. The output data rate can be either the same as the selected reference input data rate or divided to be 8 kHz.
65	PRI_LOS	Primary Reference Lost (5 V Tolerant Input). When this signal is high, it indicates that PRIMARY REFERENCE is not valid. Combined with SEC_LOS input, this input pin is used in the External Reference Switching Mode of the DPLL.
64	SEC_LOS	Secondary Reference Lost (5 V Tolerant Input). When this signal is high, it indicates that SECONDARY REFERENCE is not valid. Combined with the PRI_LOS input, this input pin is used in the External Reference Switching Mode of the DPLL.
63	C32/64o	C32/64o Clock (5 V Tolerant Output). A 32.768 MHz output clock when the DPLL Clock Monitor register bit (CKM) is low. A 65.536 MHz clock when the DPLL Clock Monitor register bit (CKM) is high.
58	C1M5o	C1.5o Clock (5 V Tolerant Output). A 1.544 MHz output clock.
60	ST_FPo0	ST-BUS Frame Pulse Output (5 V Tolerant Output). The width of this output ST-BUS frame pulse can be 244 ns, 122 ns or 61 ns. The frequency is 8 kHz.
61	ST_CKo0	ST-BUS Clock Output (5 V Tolerant Output). The frequency of this output ST-BUS clock can be 4.096 MHz, 8.192 MHz or 16.384 MHz.
30	ST_FPo1	ST-BUS Frame Pulse Output (5 V Tolerant Output). The width of this output ST-BUS frame pulse can be 244 ns, 122 ns or 61 ns. The frequency is 8 kHz.
31	ST_CKo1	ST-BUS Clock Output (5 V Tolerant Output). The frequency of this output ST-BUS clock can be 4.096 MHz, 8.192 MHz or 16.384 MHz.
254	CS	Chip Select (5 V Tolerant Input). This active low input is used by the microprocessor to access the microport.
255	DS	Data Strobe (5 V Tolerant Input). This active low input works in conjunction with CS to initiate the read and write cycles.
256	R/W	Read/Write (5 V Tolerant Input). This input controls the direction of the data bus lines (D0 - D15) during the microprocessor access.
16 to 9 and 6 to 1	A0 - A13	Address 0 - 13 (5 V Tolerant Inputs). These are the address lines to the internal memories and registers.
251 to 244 and 241 to 234	D0 - D15	Data Bus 0 - 15 (5 V Tolerant I/Os). These pins form the 16-bit data bus of the microport.
233	DTA	Data Transfer Acknowledge (5 V Tolerant Output). This active low output indicates that a data bus transfer is completed. A pull-up resistor is required to hold a high level.

Pin Description (continued)

256 Pin HQFP	Name	Description
154	$\overline{\text{PCI_OE}}$	PCI Output Enable (3.3 V Tolerant Input). This active low input is the control signal used to tristate the BSTio0 - 31 pins during hot-swapping. During normal operation this signal should be low.
25,38,39,40,47, 50,51,52,53,121, 122,123,124, 126,127,128,129, 130,131,132,133	IC_GND	Internal Connection. These pins MUST be connected to ground for normal operation.
26,27,28,29, 32,33,34,35, 41,42,	IC_OPEN	Internal Connection. These pins MUST be left open for normal operation.
80 to 87, 90 to 93, 118,157,158,165, 166,173,174, 181,182, 189 to 196 205,206,213,214, 221,222,227, 228,232	NC	No Connection. These pins MUST be left unconnected for normal operation.
24	TDi	Test Serial Data In (3.3 V Input with Internal pull-up). JTAG serial test instructions and data are shifted in on this pin. This pin is pulled high by an internal pull-up when not driven.
20	TDo	Test Serial Data Out (3.3 V Tolerant Tri-state Output). JTAG serial data is output on this pin on the falling edge of TCK. This pin is held in high impedance state when JTAG is not enabled.
22	TCK	Test Clock (5 V Tolerant Input). Provides the clock to the JTAG test logic. This pin should be low when JTAG is not enabled.
23	$\overline{\text{TRST}}$	Test Reset (3.3 V Input with Internal pull-up). Asynchronously initializes the JTAG TAP Controller by putting it in the Test-Logic-Reset state. This pin should be pulled low to ensure that the ZL50031 is in normal functional mode.
21	TMS	Test Mode Select (5 V Tolerant Input with Enabled Internal Pull-up): JTAG signal that controls the state transitions of the TAP controller. This pin is pulled high by an internal pull-up resistor when it is not driven.

1.0 Device Overview

The ZL50031 can switch up to $4,096 \times 2,048$ channels while providing a rate conversion capability. It is designed to switch 64 kbps PCM or $N \times 64$ kbps data between the backplane and local switching applications. The device maintains frame integrity in data applications and minimum throughput delay for voice applications on a per-channel basis.

The backplane interface can operate at 8.192 Mbps in CT-Bus mode or 16.384 Mbps in ST-BUS mode and is arranged in 125 μ s wide frames that contain 128 or 256 channels respectively. A built-in rate conversion circuit allows users to interface between the backplane and the local interface which operates at 2.048 Mbps, 4.096 Mbps or 8.192 Mbps.

By using Zarlink's message mode capability, the microprocessor can access input and output time slots on a per channel basis. This feature is useful for transferring control and status information for external circuits or other TDM devices.

2.0 Functional Description

A Functional Block Diagram of the ZL50031 is shown in Figure 1 on page 2. It is designed to interface CT-Bus and ST-BUS serial streams from a backplane source and ST-BUS serial streams from a local source.

3.0 Frame Alignment Timing

In the ST-BUS or the CT-Bus mode, the C8_A_io or C8_B_io pin accepts an 8.192 MHz clock for the frame pulse alignment. The FRAME_A_io or FRAME_B_io is the frame pulse signal which goes low at the frame boundary for 122 ns. The frame boundary is defined by the rising edge of the C8_A_io or C8_B_io clock during the low cycle of the frame pulse. Figure 2 shows the CT-Bus timing for the backplane 8.192 Mbps data streams and Figure 3 shows the ST-BUS timing for the 16.384 Mbps backplane data streams.

Figure 2 - CT-Bus Timing for 8 Mbps Backplane Data Streams

Figure 3 - ST-BUS Timing for 16 Mbps Backplane Data Streams

4.0 Switching Configuration

The device has two operation modes at different data rates for the backplane interface and three operation modes for the local interface. These modes can be programmed via the Device Mode Selection (DMS) register. Mode selections between the backplane and local interfaces are independent.

4.1 Backplane Interface

The backplane interface can be programmed to accept data streams of 8 Mbps or 16 Mbps. When H.110 mode is enabled, BSTio0 to BSTio31 have a data rate of 8.192 Mbps. When ST-BUS mode is enabled, BSTio0 to BSTio15 have a data rate of 16.384 Mbps. Table 1 describes the data rates and mode selections for the backplane interface.

BMS Bit of the DMS Register	Modes	Backplane Interface
0	8.192 Mbps	BSTio0 - 31
1	16.384 Mbps	BSTio0 - 15

Table 1 - Mode Selection for Backplane Streams

4.2 Local Interface

The local side of the ZL50031 is divided up into 4 groups. Group 0 contains LSTi0-3 and LSTo0-3, Group 1 contains LSTi4-7 and LSTo4-7, Group 2 contains LSTi8-11 and LSTo8-11, Group 3 contains LSTi12-15 and LSTo12-15. Each group can be selected to operate in one of three data rates, 2.048 Mbps, 4.094 Mbps and 8.192 Mbps. The per-group data rate is selected through the Device Mode Selection (DMS) register. Streams belonging to the same group have the same operation at the same data rate. See Table 2 on page 14 for a description of the data rates and mode selection for the local ST-BUS interface.

DMS Register Bits		Modes	Usable Streams
LG01	LG00		
0	0	8.192 Mbps	LSTi0 - 3, LSTo0 - 3
0	1	4.096 Mbps	
1	0	2.048 Mbps	
1	1	Reserved	

Table 2 - Mode Selection for Local LSTi0 - 3 and LSTo0 - 3 Streams, Group 0

DMS Register Bits		Modes	Usable Streams
LG11	LG10		
0	0	8.192 Mbps	LSTi4 - 7, LSTo4 - 7
0	1	4.096 Mbps	
1	0	2.048 Mbps	
1	1	Reserved	

Table 3 - Mode Selection for Local LSTi4 - 7 and LSTo4 - 7 Streams, Group 1

DMS Register Bits		Modes	Usable Streams
LG21	LG20		
0	0	8.192 Mbps	LSTi8 - 11, LSTo8 - 11
0	1	4.096 Mbps	
1	0	2.048 Mbps	
1	1	Reserved	

Table 4 - Mode Selection for Local LSTi8 - 11 and LSTo8 - 11 Streams, Group 2

DMS Register Bits		Modes	Usable Streams
LG31	LG30		
0	0	8.192 Mbps	LSTi12-15, LSTo12-15
0	1	4.096 Mbps	
1	0	2.048 Mbps	
1	1	Reserved	

Table 5 - Mode Selection for Local LSTi12 - 15 and LSTo12 - 15 Streams, Group 3

5.0 Local Input Delay Selection

The local input delay selection allows individual local input streams to be aligned and shifted against the input frame pulse (FRAME_A_io or FRAME_B_io). This feature compensates for the variable path delays in the local interface. Such delays can occur in large centralized and distributed switching systems.

Each local input stream can have its own bit delay offset value by programming the local input bit delay selection registers (LIDR0 to LIDR5). See Table 11, "Local Input Bit Delay Registers (LIDR0 to LIDR5) Bits" on page 39, for the contents of these registers. Possible bit adjustment can range up to +7 3/4 bit periods forward with resolution of 1/4 bit period. See Table 12 on page 39 and Figure 12 on page 40 for local input delay programming.

6.0 Output Advancement Selection

The ZL50031 allows users to advance individual backplane or local output streams with respect to the frame boundary. This feature is useful in compensating for variable output delays caused by various output loading conditions. Each output stream can have its own advancement value programmed by the output advancement registers. The backplane output advancement registers (BOAR0 to BOAR3) are used to program the backplane output advancement. The local output advancement registers (LOAR0 to LOAR1) are used to program the local output advancement. Possible adjustment for local and backplane output data streams is 22.5 ns with a resolution of 7.5 ns. The advancement is independent of the output data rate. Table 13 on page 41 and Figure 13, "Example of Backplane Output Advancement Timing" on page 41, and Table 14 on page 42 and Figure 14, "Local Output Advancement Timing" on page 42 describe the details of the output advancement programming for the backplane and local interfaces respectively.

7.0 Local Output Timing Considerations

The output data of the ZL50031's local side is slightly advanced with respect to the frame and bit boundary as defined by the local output clocks and frame pulses (ST_FPo0, ST_CKo0, ST_FPo1, ST_CKo1). The advancement is in the range of 5 ns to 17 ns. Despite this advancement, the ZL50031 will operate within the parameters specified in the datasheet because input data are usually sampled at the 3/4 or 1/2 point of the bit cell. However, the user should be cautious when introducing additional delay to the clock signals only (e.g., by passing them through glue logic, FPGA, or CPLD), which will introduce a few nanoseconds of delay relative to the data. If the clock signal is delayed, data will be advanced from the receiver device's point of view. This may cause errors in sampling the data. Using an example where a 3/4 sampling point is used, there is about 30 ns from the sampling point to the end of the bit cell. With a worst-case of 17 ns advancement, the timing margin will be approximately 13 ns. Any additional delays applied to the local output clocks (ST_CKo0 and ST_CKo1) must not exceed 13 ns minus the hold time of the receiving device. Delays applied to both clocks and data equally will not impact the device operation.

8.0 Memory Block Programming

The ZL50031 block programming mode (BPM) register provides users with the capability of initializing the local and backplane connection memories in two frames. Bit 13 - bit 15 of every backplane connection memory location will be programmed with the pattern stored in bit 6 - bit 8 of the BPM register. Bit 13 - bit 15 of every local connection memory location will be programmed with the pattern stored in bits 3 to 5 of the BPM register. The other bit positions of the backplane connection memory and the local connection memory are loaded with zeros. See Figure 4 on page 16 for the connection memory contents when the device is in block programming mode.

The block programming mode is enabled by setting the memory block program (MBP) bit of the Control Register to high. After the block programming enable (BPE) bit of the BPM register is set to high, the block programming data will be loaded into bits 13 to 15 of every backplane connection memory location and bits 13 to 15 of every local connection memory low location. The other connection memory bits are loaded with zeros. When the memory block programming is completed, the device resets the BPE bit to low. See Table 10 on page 37 for the bit assignment of the BPM register.

Figure 4 - Block Programming Data in the Connection Memories

9.0 Delay Through the ZL50031

The switching of information from the input serial streams to the output serial streams results in a throughput delay. The device can be programmed to perform time slot interchange functions with different throughput delay capabilities on a per-channel basis. For voice applications it is recommended to select variable throughput delay to ensure minimum delay between input and output data. In wideband data applications it is recommended to select constant throughput delay to maintain the frame integrity of the information through the switch.

The delay through the device varies according to the type of throughput delay selected in the BTM2 - BTM0 bits of the backplane connection memory or LTM0 - LTM2 bits of the local connection memory as described in Table 24 on page 51 and Table 27 on page 53, respectively.

9.1 Variable Delay Mode

The delay in this mode is dependent only on the combination of source and destination channels and is independent of input and output streams. The minimum delays achievable in the ZL50031 device are 3-channel delay, 5-channel delay, and 10-channel delay for the 2 Mbps, 4 Mbps, and 8 Mbps data rates respectively. The maximum delay is one frame plus 3 channels, one frame plus 5 channels, and one frame plus 10 channels for the 2 Mbps, 4 Mbps and 8 Mbps modes respectively.

For the backplane interface, the variable delay mode can be programmed through the backplane connection memory bits, BTM2 - BTM0. When BTM2 - BTM0 are programmed to "000", it is a per-channel variable delay from local input to the backplane output. When BTM2 - BTM0 are set to "010", it is a per-channel variable delay from backplane input to backplane output.

For the local interface, the variable delay mode can be programmed through the local connection memory low bits, LTM2 - LTM0. When LTM2 - LTM0 are programmed to "000", it is a per-channel variable delay from local input to local output. When LTM2 - LTM0 are set to "010", it is a per-channel variable delay from backplane input to local output.

9.2 Constant Delay Mode

In this mode, a multiple page data memory buffer is used to maintain frame integrity in all switching configurations such that a channel written during frame N is always read out during frame N+2.

For the backplane interface, when BTM2 - BTM0 are programmed to "001", it is a per-channel constant delay mode from local input to backplane output. When BTM2 - BTM0 are programmed to "011", it is a per-channel constant delay from backplane input to backplane output.

For the local interface, when LTM2 - LTM0 are programmed to "001", it is a per-channel constant delay mode from local input to local output. When LTM2 - LTM0 are set to "011", it is a per-channel constant delay mode from backplane input to local output.

10.0 Microprocessor Interface

The ZL50031 provides a parallel microprocessor interface for non-multiplexed bus structures. This interface is compatible with Motorola non-multiplexed bus structures. The required microprocessor signals are the 16-bit data bus (D15-D0), 14-bit address bus (A13-A0) and 4 control lines (CS, DS, R/W and DTA). See Figure 37, "Motorola Non-Multiplexed Bus Timing" on page 71 for the Motorola non-multiplexed bus timing.

The ZL50031 microprocessor port provides access to the internal registers, the connection and data memories. All locations provide read/write access except for the Local and Backplane Bit Error Rate registers (LBERR and BBERR) and Data Memory which can only be read by the users.

10.1 DTA Data Transfer Acknowledgment Pin

The DTA pin of the microprocessor is driven LOW by internal logic to indicate that a data bus transfer is completed. When the bus cycle ends, this pin switches to the high impedance state. An external pull-up of between 1 kΩ and 10 kΩ is required at this output.

11.0 Address Mapping of Memories and Registers

The address bus on the microprocessor interface selects the internal registers and memories of the ZL50031. If the address bit A13 is low, the registers are addressed by A12 to A0 as shown in Table 6 on page 17.

A13 - A0	Location
0000 _H	Control Register, CR
0001 _H	Device Mode Selection Register, DMS
0002 _H	Block Programming Mode Register, BPM
0003 _H	Reserved
0004 _H	Local Input Bit Delay Register 0, LIDR0
0005 _H	Local Input Bit Delay Register 1, LIDR1
0006 _H	Local Input Bit Delay Register 2, LIDR2
0007 _H	Local Input Bit Delay Register 3, LIDR3

Table 6 - Address Map For Internal Registers (A13 = 0)

A13 - A0	Location
0008 _H	Local Input Bit Delay Register 4, LIDR4
0009 _H	Local Input Bit Delay Register 5, LIDR5
000A _H to 001B _H	Reserved
001C _H	Backplane Output Advancement Register 0, BOAR0
001D _H	Backplane Output Advancement Register 1, BOAR1
001E _H	Backplane Output Advancement Register 2, BOAR2
001F _H	Backplane Output Advancement Register 3, BOAR3
0020 _H	Local Output Advancement Register 0, LOAR0
0021 _H	Local Output Advancement Register 1, LOAR1
0022 _H to 0026 _H	Reserved
0027 _H	Local BER Input Selection Register, LBIS
0028 _H	Local BER Register, LBERR
0029 _H	Backplane BER Input Selection Register, BBIS
002A _H	Backplane BER Register, BBERR
002B _H	DPLL Operation Mode Register 1, DOM1
002C _H	DPLL Operation Mode Register 2, DOM2
002D _H	DPLL Output Adjustment Register, DPOA
002E _H	DPLL House Keeping Register, DHKR

Table 6 - Address Map For Internal Registers (A13 = 0) (continued)

If A13 is high, the remaining address input lines are used to select the data and connection memory positions corresponding to the serial input or output data streams as shown in Table 7 on page 19.

The Control register (CR), the Device Mode Selection register (DMS) and the Block Programming Mode register (BPM) control all the major functions of the device. The DMS and BPM should be programmed immediately after system power up to establish the desired switching configuration. The Control register is used to select Data or Connection Memory for microport operations, ST-BUS output frame and clock modes, and to set Memory Block Programming and Bit Error Rate Testing.

The Control register (CR) consists of the memory block programming bit (MBP) and the memory select bits (MS2-0). The memory block programming bit allows users to program the entire connection memory in two frames (See Section 8.0, "Memory Block Programming" on page 16). The memory select bits control the selection of the connection memories or the data memories. See Table 8 on page 35 for contents of the Control register.

The DMS register consists of the backplane and the local mode selection bits (BMS, LG31 - LG30, LG21 - LG20, LG11 - LG10 and LG01 - LG00) that are used to enable various switching modes for the backplane and the local interfaces respectively. See Table 9 on page 36 for the content of the DMS register.

The BPM register consists of the block programming data bits (LBPD2-0 and BBPD2-0) and the block programming enable bit (BPE). The block programming enable bit allows users to program the entire backplane and local connection memories in two frames (see section 8.0, "Memory Block Programming" on page 16). If the ODE pin is low, the backplane CT-Bus is in input mode and the local output drivers are in high impedance state. If the ODE pin

is high, all the backplane CT-Bus and local ST-BUS I/O drivers are controlled on a per-channel basis by backplane and local connection memories, respectively. By programming BTM2-0 bits to “110” in the backplane connection memory, the user can control the per-channel input (can be used for high impedance) on the backplane interface. For the local interface, users can program LTM2 -0 bits to “110” in the local connection memory to control the per-channel input (can be used for high impedance). See Table 10 on page 37 for the content of the BPM register.

A13 (Note 1)	Stream Address (ST0-31)						Channel Address (Ch0-255)								
	A12	A11	A10	A9	A8	Stream #	A7	A6	A5	A4	A3	A2	A1	A0	Channel #

1	1	1	1	1	1	Stream 31	1	1	1	1	1	1	1	1	Ch 255 (Note 5)

Notes:
 1. A13 must be high for access to data and connection memory positions. A13 must be low for access to registers.
 2. Channels 0 to 31 are used when serial stream is at 2 Mbps.
 3. Channels 0 to 63 are used when serial stream is at 4 Mbps.
 4. Channels 0 to 127 are used when serial stream is at 8 Mbps.
 5. Channels 0 to 255 are used when serial stream is at 16 Mbps.
 6. The local side uses Streams 0 to 15 only while the backplane uses streams 0 to 31.

Table 7 - Address Map for Memory Locations (A13 = 1)

12.0 Backplane Connection Memory

The backplane connection memory controls the switching configuration of the backplane interface. Locations in the backplane connection memory are associated with particular BSTio streams.

The BTM2 - 0 bits of each backplane connection memory entry allow the per-channel selection from message mode, connection mode, constant delay, variable delay or bit error test mode. The backplane connection memory is also where the BSTio channels are set to be either inputs or outputs. See Table 24 on page 51 for the per-channel control functions.

In the switching mode, the contents of the backplane connection memory stream address bits (BSAB4-0) and channel address bits (BCAB7-0) define the source information (stream and channel) of the time slot that will be switched to the backplane BSTio streams. During message mode, the 8 least significant bits of the backplane connection memory will be transferred to the BSTio pins.

13.0 Local Connection Memory

The local connection memory controls the local interface switching configuration. Locations in the local connection memory are associated with particular LSTo streams.

The LTM2 - 0 bits of each local connection memory entry allow the per-channel selection from message mode, connection mode, constant delay, variable delay or bit error test mode. See Table 27 on page 53 for the per-channel control functions.

In the switching mode, the contents of the local connection memory stream address bits (LSAB4-0) and the channel address bits (LCAB7-0) define the source information (stream and channel) of the time slot that will be switched to the local LSTo streams. During message mode, only the 8 least significant bits of the local connection memory low bits are transferred to the LSTo pins.

14.0 Bit Error Rate Test

The ZL50031 offers users a Bit Error Rate (BER) test feature for the backplane and the local interfaces. The circuitry of the BER test consists of a transmitter and a receiver on both interfaces that can transmit and receive the BER patterns independently. The transmitter can output a pseudo-random pattern of the form $2^{15} - 1$ to any channel and any stream within a frame. For the test, users can program the output channel and stream through the backplane or local connection memory and the input channel and stream using Local or Backplane BER Input Selection (BIS) registers. See Table 15 on page 43 and Table 17 on page 43 for the LBIS and the BBIS registers contents, respectively.

The receiver receives the BER pattern and does an internal BER pattern comparison. For backplane interface, the comparison result is stored in the Backplane BER register (BBERR). For local interface, the result is stored in the Local BER register (LBERR).

15.0 DPLL

The Digital Phase Locked Loop (DPLL) accepts selectable 2.048 MHz, 1.544 MHz or 8 kHz input reference signals. It accepts reference inputs from independent sources and provides bit-error-free reference switching. The DPLL meets phase slope and MTIE requirements defined by the Telcordia GR-1244-CORE standard.

The DPLL also provides the timing for the rest of the ZL50031 Digital Switch, generating several network clocks with the appropriate quality. Clocks are synchronized to one of two input reference clocks and meet the requirements of the H.110 clock specification.

15.1 ZL50031 Modes of Operation

The DPLL, and consequently the ZL50031, can, as required by the H.110 standard, operate in three different modes: Primary Master, Secondary Master and Slave. See Figure 5, "Typical Timing Control Configuration" on page 21.

To configure the DPLL, there are two Operation Mode registers: DOM1 and DOM2. See Table 19 on page 44 and Table 20 on page 47 for the contents of these registers.

In all modes the ZL50031 monitors both the "A Clocks" (C8_A_io and FRAME_A_io) and the "B Clocks" (C8_B_io and FRAME_B_io). The Fail_A and the Fail_B signals indicate the quality of the "A Clocks" and "B Clocks" respectively.

Figure 5 - Typical Timing Control Configuration

15.1.1 Primary Master Mode

In the Primary Master Mode, the ZL50031 drives the “A Clocks” (C8_A_io and FRAME_A_io), by locking to the primary reference (PRI_REF). The PRI_REF can be provided by one of the locally derived network reference sources (LREF0-3), the CTREF1 input or the CTREF2 input. In this mode the ZL50031 has the ability to monitor the primary reference. If the primary reference becomes unreliable, the device continues driving “A Clocks” in stable Holdover Mode until it makes a Stratum 4 Enhanced compatible switch to the secondary reference (SEC_REF) for its network timing. The secondary reference can be provided by one of the local network references (LREF0-3), CTREF1 or CTREF2.

If the primary reference comes back or recovers, the ZL50031 makes a Stratum 4 Enhanced compatible switch back to the original primary reference and the system returns to normal operation state.

If necessary, the ZL50031 can be prevented from switching back to the original primary reference by programming the RPS bit in DOM1 register to give preference to the secondary reference.

While in the Primary Master mode, the ZL50031 attenuates jitter and wander above 1.52 Hz from the selected input reference clock and generates all output clocks according to the DPLL jitter transfer function diagram on Figure 10 on page 31 and Figure 11 on page 32.

For the Primary Master mode selection, see Table 21, “ZL50031 Mode Selection - By Programming DOM1 and DOM2 Registers” on page 49.

15.1.2 Secondary Master Mode

In the Secondary Master Mode, the ZL50031 drives the “B Clocks” (C8_B_io and FRAME_B_io), by locking to the “A Clocks”. As required by the H.110 standard, the “B Clocks” are edge-synchronous with the “A Clocks”, as long as jitter on the “A Clocks” meets Telcordia GR-1244-CORE specifications.

If the “A Clocks” become unreliable, system software is notified and the ZL50031 continues driving the “B Clocks” in stable Holdover Mode until it makes a Stratum 4 Enhanced compatible switch to the secondary reference (SEC_REF) for its network timing. The secondary reference can be a local network reference (LREF0-3), CTREF1 or CTREF2. If the “A Clocks” cannot recover, the designated secondary master can be promoted to primary master by system software. This promotion will cause the “B Clocks” to assume the role of the “A Clocks”.

For the Secondary Master mode selection, see Table 21, "ZL50031 Mode Selection - By Programming DOM1 and DOM2 Registers" on page 49.

15.1.3 Slave Mode

In the Slave Mode, the ZL50031 is phase locked to the “A Clocks”. If the “A Clocks” become unreliable, the device goes to stable Holdover Mode until it makes a Stratum 4 Enhanced compatible switch to the “B Clocks”. The ZL50031 will perform all required functionality as long as the “A Clocks” and the “B Clocks” conform to the Telcordia GR-1244-CORE jitter specifications.

In addition, the device can be used to generate a NREFo reference from its network references, LREF0-3. In most systems NREFo is connected to either CT_REF1 or CT_REF2.

While the device is in Slave Mode and the “A Clocks” or the “B Clocks” do not recover, the designated slave can be promoted to secondary master by system software. In that case, the network reference can be used as the secondary reference.

Table 21 on page 49 shows how to program the DOM1 and DOM2 registers to enable the Slave Mode of the ZL50031.

16.0 DPLL Functional Description

Figure 6 - DPLL Functional Block Diagram

16.1 Reference Select and Frequency Mode MUX Circuits

The DPLL accepts two simultaneous reference input signals and operates on their rising edges. Either the primary reference (PRI_REF) signal or the secondary reference (SEC_REF) signal can be selected to be the reference signal (REF) to the PLL circuit. The appropriate frequency mode input (either `FREQ_MOD_PRI` or `FREQ_MOD_SEC`) is selected to be the input of the PLL circuit. The selection is done by the State Machine Circuit based on the current state.

The `FREQ_MOD_PRI` and the `FREQ_MOD_SEC` are 2-bit wide inputs which reflect the value in the FP1-0 and FS1-0 bits of the DOM1 register. The primary and the secondary references operate independently from each other and can have different frequencies. Switching the reference from one frequency to another does not require the device reset to be applied. Table 19 on page 44 shows input frequency selection for the primary and secondary reference respectively.

16.2 PRI and SEC MUX Circuits

The DPLL has four different modes to handle reference failure. These modes are selected by the FDM0 and FDM1 bits of the DOM2 Register. If FDM1-0 is '10' then the Primary reference is always used regardless of failures. If FDM1-0 is '11' then the Secondary reference is always used regardless of failures. Otherwise the DPLL operates in one of two failure detection modes: Autodetect or Manual detection mode. When the FDM0 and FDM1 bits are set to low in the DOM2 register ('00'), the DPLL is in the Autodetect Mode. In this mode, the outputs from the Reference Monitor Circuits LOS_PRI and LOS_SEC are used by the State Machine Circuit. When the FDM0 bit is set to high and FDM1 bit is set to low ('01'), the DPLL is in the Manual Detection Mode and the LOS_PRI and LOS_SEC signals are selected from the PRI_LOS and SEC_LOS input pins to be used by the State Machine Circuit. See Table 20 on page 47 for selection of the Failure Detection Modes.

16.3 Frame Select MUX

When the "A Clocks" or the "B Clocks" are selected as the input reference, an 8.192 MHz clock (either C8_A_io or C8_B_io) is provided to be the input reference to the PLL circuit. Because the output frame pulse (CT_FRAME) must be aligned with the selected input frame pulse, the appropriate frame pulse (either FRAME_A_io or FRAME_B_io) is selected in the Frame Select MUX circuit to be the input of the PLL circuit.

16.4 CT Clock and Frame Monitor Circuits

The CT Clock and Frame Monitor circuits check the period of the C8_A_io and the C8_B_io clocks and the FRAME_A_io and FRAME_B_io frame pulses. According to the H.110 specification, the C8 period is 122 ns with a tolerance of +/-35 ns measured between rising edges. If C8 falls outside the range of [87 ns, 157 ns], the clock is rejected and the fail signal (FAIL_A or FAIL_B) becomes high. The Frame pulse period is measured with respect to the C8 clock. The frame pulse period must have exactly 1024 C8 cycles. Otherwise, the fail signal (FAIL_A or FAIL_B) becomes high. When the CT BUS clock and frame pulse signals return to normal, the FAIL_A or FAIL_B signal returns to logic low.

16.5 Reference Monitor Circuits

There are two Reference Monitor Circuits: one for the primary reference (PRI_REF) and one for the secondary reference (SEC_REF). These two circuits monitor the selected input reference signals and detect failures by setting up the appropriate fail outputs (SLS and PLS bits in the DHKR register, see Table 23 on page 50). These fail signals are used in the Autodetect mode as the LOS_PRI and LOS_SEC signals to indicate when the reference has failed. The method of generating a failure depends on the selected reference.

When the selected reference frequency is 8.192 MHz ("A Clocks" or "B Clocks"), the fail signals are passed through from the CT Clock and Frame Monitor circuit outputs FAIL_A and FAIL_B, and used directly to set the SLS and PLS bits, accordingly.

For all other reference frequencies (8 kHz, 1.544 MHz and 2.048 MHz), the following checks are performed:

- For all references, the "minimum 90 ns" check is done. This is required by the H.110 specifications - both low level and high level of the reference must last for minimum 90 ns each.
- The "period in the specified range" check is done for all references. The length of the period of the selected input reference is checked to verify if it is in the specified range. For the E1 (2.048 MHz clock) or the T1 (1.544 MHz clock) reference, the period of the clock can vary within the range of 1 +/- 1/4 of the defined clock period which is 488 ns for the E1 clock and 648 ns for T1 clock. For the 8 kHz reference, the variation is from 1 +/- 1/32 period.
- If the selected reference is E1 or T1, "64 periods in the specified range" check is done. The selected reference is observed for a long period (64 reference clock cycles) and checked to verify if it is within the specified range - from 62 to 66 clock periods.

These reference signal verifications include a complete loss or a large frequency shift of the selected reference signal. When the reference signal returns to normal, the LOS_PRI and LOS_SEC signals will return to logic low.

16.6 State Machine Circuit

The State Machine handles the reference selection. Depending on REF_SEL and LOS signals (selection between primary reference failure and PRI_LOS and between secondary reference failure and SEC_LOS), the state machine selects PRI_REF or SEC_REF as the current input reference and dictates the PLL Circuit mode: Normal or Holdover Mode. In the Normal Mode, the DPLL output clocks are locked to the selected input reference (PRI_REF or SEC_REF). In the Holdover Mode, the DPLL clocks retain the phase and frequency values they had 32 to 64 ms prior to moving from the Normal to the Holdover Mode. When going from the Holdover to the Normal Mode, the State Machine activates the MTIE circuit and goes through the states MTIE PRI or MTIE SEC to prevent a phase shift of the output clocks during the DPLL reference switch (from PRI_REF to SEC_REF and vice versa). The state diagram is given in Figure 7, "State Machine Diagram" on page 25.

Figure 7 - State Machine Diagram

16.7 Modes of Operation

The DPLL can operate in two main modes: Normal and Holdover Mode. Each of these modes has two states: primary or secondary state. The state depends on which reference is currently selected as the preferred reference PRI_REF or SEC_REF.

16.7.1 Normal Mode

Normal Mode is typically used when a clock source synchronized to the network is required.

In the Normal Mode, the DPLL provides timing (C32/64, CT_C8, C2M and C1M5o) and frame synchronization (CT_FRAME) signals which are synchronized to one of two input references (PRI_REF or SEC_REF). The input reference signal may have a nominal frequency of 8 kHz, 1.544 MHz, 2.048 MHz or 8.192 MHz.

From a device reset condition or after reference switch, the DPLL can take up to 50 seconds to phase lock the output signals to the selected input reference signal.

16.7.2 Holdover Mode

Holdover Mode is typically used for short durations while network synchronization is temporarily disrupted.

If the FDM1-0 bits are programmed to '01' in the DOM2 register and the PRI_LOS and SEC_LOS pins are high, the DPLL is in the Holdover Mode. The DPLL can also be in the Holdover Mode if the FDM1-0 bits are programmed to '00' and the SLS and PLS bit are observed as '11' in the DPLL House Keeping Register (DHKR).

In the Holdover Mode, the DPLL provides timing and synchronization signals which are based on storage techniques and are not locked to an external reference signal. The storage value is determined while the device is in Normal Mode and locked to an external reference signal. When the DPLL is in the Normal Mode and locks to the input reference signal, a numerical value corresponding to the DPLL output reference frequency is stored alternately in two memory locations every 32 ms. When the device is switched into the Holdover Mode, the value in memory from between 32 ms and 64 ms ago is used to set the output frequency of the device.

The frequency stability of the Holdover Mode is ± 0.07 ppm, which translates to a worst case 49 frame (125 μ s) slips in 24 hours.

Two factors affect the frequency stability of the Holdover Mode. The first factor is the drift on the frequency of the master clock (C20i) while in the Holdover Mode. Drift on the master clock directly affects the Holdover Mode stability. Note that the absolute master clock stability does not affect the Holdover Frequency stability, only the change in C20i stability while in Holdover. For example, a ± 32 ppm master clock may have a temperature coefficient of ± 0.1 ppm/°C. So a 10 degree change in temperature, while the DPLL is in the Holdover Mode may result in an additional offset (over the ± 0.07 ppm) in frequency stability of ± 1 ppm, which is much greater than the ± 0.07 ppm of the DPLL. The second factor affecting Holdover frequency stability is large jitter on the reference input prior to the mode switch.

16.7.3 Freerun Mode

When the DPLL is in the Holdover Mode and the HRST bit of the DOM2 register is pulsed logic high (or held high continuously), the device is in Freerun Mode.

In Freerun Mode, the DPLL provides timing and synchronization signals which are based on the frequency of the master clock (C20i) only, and are not synchronized to the reference input signals. The frequency of the output signals is an ideal frequency with the freerun accuracy of -0.03 ppm plus the accuracy of the master clock (i.e., CT_C8 has frequency of 8.192 MHz +/- C20i_accuracy - 0.03 ppm).

Freerun Mode is typically used when a master clock source is required, or immediately following system power-up before network synchronization is achieved.

17.0 Phase Locked Loop (PLL) Circuit

As shown in Figure 8, "Block Diagram of the PLL Module" on page 27, the PLL module consists of a Skew Control, Maximum Time Interval Error (MTIE), Phase Detector, Phase Offset Adder, Phase Slope Limiter, Loop Filter, Digitally Controlled Oscillator (DCO), Divider and Frequency Select MUX modules.

Figure 8 - Block Diagram of the PLL Module

17.1 Skew Control

The circuit delays a selected reference input with a tapped delay line with seven taps - see Figure 9, "Skew Control Circuit Diagram" on page 27. The maximum delay of the per unit delay element is factored at intervals of 3.5 ns. The tap is selected by the SKEW_CONTROL bus which is programmed by the SKC2-SKC0 bits of the DPLL Output Adjustment (DPOA) register. The skew of this input will result in a static phase offset which varies from 0 to 7 steps of the maximum delay per unit delay element, between the input and the outputs of the DPLL.

Figure 9 - Skew Control Circuit Diagram

17.2 Maximum Time Interval Error (MTIE)

The MTIE circuit prevents any significant change in the output clock phase during a reference switch. Because the input references can have any relationship between their phases and the output follows the selected input reference, any switch from one reference to another could cause a large phase jump in the output clock if such a circuit did not exist. This large phase jump could cause significant data loss. The MTIE circuit keeps the phase difference between the output clock of the DPLL and the input reference the same as if the reference switch had not taken place.

During a reference switch, the State Machine module first changes the mode of the DPLL from the Normal to the Holdover Mode. In the Holdover Mode, the DPLL no longer uses the virtual reference signal, but generates very accurate outputs using storage techniques.

Because the input reference coming from the Skew Control circuit is asynchronous to the sampling clock used in the MTIE circuit, a phase error may exist between the selected input reference signal and the output signal of the DPLL. In the worst case, the Maximum Time Interval Error (MTIE) is one period of the internally used clock cycle (65.536 MHz if the selected reference frequency is 8 kHz, 2.048 MHz and 8.192 MHz, and 49.408 MHz when the selected reference frequency is 1.544 MHz). This phase error is a function of the difference in phase between the two input reference signals during reference rearrangements. Each time a reference switch is made, the delay between the input signal and the output signal can change. The value of this delay is the accumulation of the error measured during each reference switch. After many switches from one reference to another, the delay between the selected input reference and the DPLL output clocks can become unacceptably large. The user should provide MTIE reset (set MRST bit in the DOM2 register to high) causing output clocks to align to the nearest edge of the selected input reference. It is recommended that the MTIE is reset after multiple reference switchings and the device falls back to its initial reference. The MTIE **MUST** be kept in the reset mode when the ZL50031 is operating in the slave mode.

17.3 Phase Detector

The Phase Detector circuit compares the virtual reference signal from the MTIE Circuit with the feedback signal from the Frequency Select MUX circuit with respect to their rising edges, and provides an error signal corresponding to the phase difference between the two. This error signal is passed to the Phase Offset Adder Circuit. The Frequency Select MUX allows the proper feedback signal to be selected (e.g., 8 kHz, 1.544 MHz, 2.048 MHz or 8.192 MHz).

17.4 Phase Offset Adder

The Phase Offset Adder Circuit adds the PHASE_OFFSET word (bits POS6-POS0 of the DPLL Output Adjustment register - see Table 22 on page 50) to the error signal from the Phase Detector circuit to create the final phase error. This value is passed to the Phase Slope Limiter circuit. The PHASE_OFFSET word can be positive or negative. Since the PLL will stabilize to a situation where the average of the sum of the phase offset word and the phase detector output is zero, a nonzero value in the input of the Phase Offset Adder circuit will result in a static phase offset between the input and output signals of the DPLL.

Together with the Skew Control bits (SKC2-0), users can program a static phase offset between -960 ns and +990 ns if the selected input reference of the DPLL is either 8 kHz or 2.048 MHz. If the selected reference is 1.544 MHz, the programmable phase offset is between -1.27 μ s and 1.30 μ s. For the programmable ranges mentioned above, the resolution is 1.9 ns per step. See Table 22 on page 50 for the content of the DPOA register.

When the selected input reference frequency of the DPLL is 8.192 MHz ("A Clocks" or "B Clocks" are selected as the reference), the Phase Offset Adder is bypassed. The output of the Phase Detector circuit is connected directly to the input of the Phase Slope Limiter circuit. When an 8.192 MHz clock (C8_A_io or C8_B_io) is used as the reference in the Secondary Master or the Slave mode, the H.110 standard requires the output clock to always follow the input reference on an edge-to-edge basis, so the static phase offset is not required.

17.5 Phase Slope Limiter

The limiter receives the error signal from the Phase Offset Adder circuit and ensures that the DPLL responds to all input transient conditions with a maximum output phase slope of 7.6 ns per 125 μ s. Because of this slope, the ZL50031 is within the maximum phase slope of 81 ns per 1.326 ms specified by the Telcordia GR-1244-CORE standard.

The frequency stability of the Holdover Mode is ± 0.07 ppm, which translates to a worst case 49 frame (125 μ s) slips in 24 hours. This is better than the Telcordia GR-1244-CORE Stratum 3 requirement of ± 0.37 ppm (255 frame slips per 24 hours).

17.6 Loop Filter

The Loop Filter circuit gives frequency offset to the DCO circuit, based on the phase difference between the input and the feedback reference. It is similar to a first order low pass filter, with two positions for cut-off frequency (-3 dB attenuation) depending on the selected reference frequency, and it largely determines the jitter transfer function of the DPLL.

In Primary Master mode when the selected input reference frequency is 2.048 MHz, 1.544 MHz or 8 kHz, the cut-off frequency is approximately at 1.52 Hz and all the reference variations, including jitter, are attenuated according to the DPLL jitter transfer function (see Figure 10, "DPLL Jitter Transfer Function Diagram - Wide Range of Frequencies" on page 31 and Figure 11, "Detailed DPLL Jitter Transfer Function Diagram" on page 32). The Loop Filter circuit ensures that the jitter transfer requirements in ETS 300-011 and Telecordia GR-499-CORE are met when the selected reference frequency is 2.048 MHz, 1.544 MHz or 8 kHz.

When the selected input reference frequency is 8.192 MHz (i.e., in Secondary Master or Slave modes), the reference variations are bypassed to the output clocks. The cut-off frequency is at about 100 kHz, well beyond 500 Hz, the corner frequency of the Telcordia GR-1244-CORE input jitter tolerance curve.

The storage techniques, which enable generating very accurate output frequencies during the Holdover Mode of DPLL, are built into the Loop Filter circuit. When no jitter is presented on the selected input reference, the holdover frequency stability is 0.007 ppm.

17.7 Digitally Controlled Oscillator (DCO)

The DCO circuit adds frequency offset from the Loop Filter (which represents the phase error between the input and the feedback reference), to the ideal center frequency value and generates an appropriately corrected output high speed clock.

In the Normal Mode, the DCO circuit provides an output signal which is frequency and phase locked to the selected input reference signal.

In the Holdover Mode, the DCO circuit is running at a frequency that is equal to the frequency which was generated by the DCO circuit when the DPLL was in the Normal Mode.

In the Freerun Mode, the DCO circuit is freerunning at its center frequency with an output accuracy equal to the accuracy of the device master clock (C20i).

17.8 Divider

The Divider Circuit divides the DCO output frequency down to the required outputs. The following outputs are generated:

- C64 (65.536 MHz clock) - used as the internal clock for the ZL50031 device.
- CT_C8 (8.192 MHz clock), C2M (2.048 MHz clock), C1M5o (1.544 MHz clock) and CT_FRAME (8 kHz negative frame pulse) - feedback reference signals to the Frequency Select MUX Circuit.

The CT_FRAME and the CT_C8 are required clocks. C1M5o is provided as an output clock of the ZL50031.

The duty cycle of all output signals is independent of the duty cycle of the device master clock, C20i. The CT_C8, C2M and C1M5o clocks have nominal 50% duty cycle,

The output frame pulse (CT_FRAME) is generated in such a way that it is always aligned with the CT_C8 clock to form the required H.110 CT Bus clock and frame pulse shape (when the CT_FRAME is low the rising edge of the CT_C8 defines the frame boundary). Depending on the selected input reference frequency, the CT_FRAME is generated in the following way:

- When the input reference frequency is 8 kHz, the output frame pulse is aligned with the rising edge of the reference.

- When the reference frequency is either 2.048 MHz or 1.544 MHz, the CT_FRAME randomly defines the output frame boundary, always keeping the described relation to the CT_C8 clock.
- When the reference frequency is 8.192 MHz, the output frame pulse (CT_FRAME) has to be aligned with the input frame pulse (FRAME_A_io or FRAME_B_io). Since an 8.192 MHz clock (either C8_A_io or C8_B_io) is used as the reference clock, the selected frame pulse from the Frame Select MUX is provided as the input to the Divider circuit and the CT_FRAME is synchronized to it.

17.9 Frequency Select MUX Circuit

According to the selected input reference of the DPLL, this MUX will select the appropriate output frequency to be the feedback signal to the PLL and MTIE Circuits.

18.0 Measures of Performance

The following are some the DPLL performance indicators and their corresponding definitions.

18.1 Intrinsic Output Jitter

Intrinsic jitter is the jitter produced by the synchronizing circuit and is measured at its output. It is measured by applying a reference signal with no jitter to the input of the device, and measuring its output jitter. Intrinsic jitter may also be measured when the device is in a non-synchronizing mode, such as freerun or holdover, by measuring the output jitter of the device. Intrinsic jitter is usually measured with various band-limiting filters depending on the applicable standards. See "AC Electrical Characteristics†- Output Clock Jitter Generation (Unfiltered)" on page 64 for jitter values.

18.2 Jitter Tolerance

Jitter tolerance is a measure of the ability of a PLL to operate properly without cycle slips (i.e., remain in lock and regain lock in the presence of large jitter magnitudes at various jitter frequencies) when jitter is applied to its reference. The applied jitter magnitude and the jitter frequency depend on the applicable standards. The input jitter tolerance of the DPLL depends on the selected reference frequency and can not exceed: ± 15 U.I. for E1 or T1 references, and ± 1 U.I. for 8 kHz references.

18.3 Jitter Transfer

Jitter transfer or jitter attenuation refers to the magnitude of jitter at the output of a device for a given amount of jitter at the input of the device. Input jitter is applied at various amplitudes and frequencies, and output jitter is measured with various filters depending on the applicable standards.

In slave and secondary master mode the H.110 standard requires the "B Clocks" to be edge-synchronous with the "A Clocks", as long as jitter on the "A Clocks" meets Telcordia GR-1244-CORE specifications. Therefore in these two modes no jitter attenuation is performed.

In primary master mode the jitter attenuation of the DPLL is determined by the internal 1.52 Hz low pass Loop Filter and the Phase Slope Limiter. Figure 10, "DPLL Jitter Transfer Function Diagram - Wide Range of Frequencies" on page 31 shows the DPLL jitter transfer function diagram in a wide range of frequencies, while Figure 11, "Detailed DPLL Jitter Transfer Function Diagram" on page 32 is the portion of the diagram from Figure 10 around 0 dB of the jitter transfer amplitude. At this point it is possible to see that when operating in primary master mode the DPLL is a second order, type 2 PLL. The jitter transfer function can be described as a low pass filter to 1.52 Hz - 20 dB/decade, with peaking less than 0.5 dB.

All outputs are derived from the same signal, therefore these diagrams apply to all outputs. Since 1 U.I. at 1.544 MHz (648 ns_{pp}) is not equal to 1 U.I. at 2.048 MHz (488 ns_{pp}), a transfer value using different input and output frequencies must be calculated in common units (e.g., seconds) as shown in the following example:

What is the T1 and E1 output jitter when the T1 input jitter is 20 U.I. (T1 U.I. Units) and the T1 to T1 jitter attenuation is 18 dB, for a given jittering frequency?

$$\begin{aligned} \text{OutputT1} &= \text{InputT1} \times 10^{\left(\frac{-A}{20}\right)} \\ \text{OutputT1} &= 20 \times 10^{\left(\frac{-18}{20}\right)} = 2.5 \text{UI(T1)} \\ \text{OutputE1} &= \text{OutputT1} \times \frac{(1 \text{UIT1})}{(1 \text{UIE1})} \\ \text{OutputE1} &= \text{OutputT1} \times \frac{(644 \text{ns})}{(488 \text{ns})} = 3.3 \text{UI(T1)} \end{aligned}$$

Using the method mentioned above, the jitter attenuation can be calculated for all combinations of inputs and outputs.

Because intrinsic jitter is always present, the jitter attenuation will appear to be lower for small input jitter signals than for large ones. Consequently, accurate jitter transfer function measurements are usually made with large input jitter signals (e.g., 75% of the specified maximum jitter tolerance).

Figure 10 - DPLL Jitter Transfer Function Diagram - Wide Range of Frequencies

Figure 11 - Detailed DPLL Jitter Transfer Function Diagram

18.4 Frequency Accuracy

Frequency accuracy is defined as the absolute tolerance of an output clock signal when the DPLL is not locked to an external reference, but is operating in the Freerun Mode. Because the output of the DCO Circuit has only discrete values, the output frequency of the DPLL has the limited accuracy of 0.03 ppm based upon the design implementation. In addition, the master clock (C20i) accuracy also directly affects the freerun accuracy. The freerun accuracy is then, 0.03 ppm plus the master clock accuracy.

18.5 Holdover Frequency Stability

Holdover frequency stability is defined as the maximum fractional frequency offset of an output clock signal when it is operating using a stored frequency value. For the DPLL, the stored value is determined while the device is in Normal Mode and locked to an external reference signal. As a result, when the DPLL is in the Normal Mode, the stability of the master clock (C20i) does not affect the holdover frequency stability because the DPLL will compensate for master clock changes while in Normal Mode. However, when the DPLL is in the Holdover Mode, the stability of the master clock does affect the Holdover frequency stability. The holdover frequency stability is 0.07 ppm assuming that the C20i frequency is held constant.

18.6 Locking Range

The locking range is the input frequency range over which the DPLL must be able to pull into synchronization and to maintain the synchronization. The locking range is defined by the Loop Filter Circuit and is equal to +/- 298 ppm.

Note that the locking range is related to the master clock (C20i). If the master clock is shifted by -100 ppm, the whole locking range also shifts -100 ppm downwards to be: -398 ppm to 198 ppm.

18.7 Phase Slope

The phase slope or the phase alignment speed is the rate at which a given signal changes phase with respect to an ideal signal. The given signal is typically the output signal. The ideal signal is of constant frequency and is nominally equal to the value of the final output signal or final input signal. Many telecom standards like Telcordia GR-1244-CORE state that the phase slope may not exceed a certain value, usually 81 ns/1.327 ms (61 ppm). This can be achieved by limiting the phase detector output to 61 ppm or less.

When operating in primary master mode, the Phase Slope Limiter Circuit achieves the maximum phase slope of 56 ppm or 7.0 ns/125 μ s. When operating in secondary master or slave mode, the output edges follow the input edges in accordance with the H.110 standard.

18.8 Maximum Time Interval Error (MTIE)

MTIE is the maximum peak to peak delay between a given timing signal and an ideal timing signal within a particular observation period.

For the DPLL, the maximum time interval error is less than 21 ns per reference switch.

18.9 Phase Lock Time

The Phase Lock Time is the time it takes the PLL to phase lock to the input signal. Phase lock occurs when the input and the output signals are not changing in phase with respect to each other (not including jitter).

Lock time is very difficult to determine because it is affected by many factors which include:

- initial input to output phase difference
- initial input to output frequency difference
- PLL loop filter
- PLL limiter

Although a short phase lock time is desirable, it is not always possible to achieve due to other PLL requirements. For instance, better jitter transfer performance is achieved with a lower frequency loop filter which increases lock time, but better (smaller) phase slope performance (limiter) results in longer lock times. The DPLL loop filter and limiter were optimized to meet the Telcordia GR-499-CORE jitter transfer and Telcordia GR-1244-CORE phase alignment speed requirements. Consequently, phase lock time, which is not a standards requirement, is less than 50 seconds.

19.0 Initialization of the ZL50031

During power up, the $\overline{\text{TRST}}$ pin should be pulled low to ensure that the ZL50031 is in the functional mode. An external pull-down resistor is required on this pin so that the ZL50031 will not enter the JTAG test mode during power up.

After power up, the contents of the connection memory can be in any state. The ODE pin should be held low after power up to keep all serial outputs in a high impedance state until the microprocessor has initialized the switching matrix. This procedure prevents two serial outputs from driving the same stream simultaneously.

During the microprocessor initialization routine, the microprocessor should program the desired active paths through the switch. The memory block programming feature can also be used to quickly initialize the backplane and local connection memories.

When this process is completed, the microprocessor controlling the ZL50031 can bring the ODE pin high to relinquish the high impedance state control.

20.0 JTAG Support

The ZL50031 JTAG interface conforms to the Boundary-Scan IEEE1149.1 standard. The operation of the boundary-scan circuitry is controlled by an external Test Access Port (TAP) Controller.

20.1 Test Access Port (TAP)

The Test Access Port (TAP) accesses the ZL50031 test functions. It consists of three input pins and one output pin as follows:

- **Test Clock Input (TCK)** - TCK provides the clock for the test logic. The TCK does not interfere with any on-chip clock and thus remains independent in the functional mode. The TCK permits shifting of test data into or out of the Boundary-Scan register cells concurrently with the operation of the device and without interfering with the on-chip logic.
- **Test Mode Select Input (TMS)** - The TAP Controller uses the logic signals received at the TMS input to control test operations. The TMS signals are sampled at the rising edge of the TCK pulse. This pin is internally pulled to Vdd when it is not driven from an external source.
- **Test Data Input (TDi)** - Serial input data applied to this port is fed either into the instruction register or into a test data register, depending on the sequence previously applied to the TMS input. Both registers are described in a subsequent section. The received input data is sampled at the rising edge of TCK pulses. This pin is internally pulled to Vdd when it is not driven from an external source.
- **Test Data Output (TDO)** - Depending on the sequence previously applied to the TMS input, the contents of either the instruction register or data register are serially shifted out towards the TDO. The data out of the TDO is clocked on the falling edge of the TCK pulses. When no data is shifted through the boundary scan cells, the TDO driver is set to a high impedance state.
- **Test Reset (TRST)** - Resets the JTAG scan structure. This pin is internally pulled to Vdd when it is not driven from an external source. An external pull-down resistor is required on this pin so that the ZL50031 will not enter the JTAG test mode during power up.

20.2 Instruction Register

The ZL50031 uses the public instructions defined in the IEEE 1149.1 standard. The JTAG Interface contains a four-bit instruction register. Instructions are serially loaded into the instruction register from TDi when the TAP Controller is in its shifted-IR state. These instructions are subsequently decoded to achieve two basic functions: to select the test data register that may operate while the instruction is current and to define the serial test data register path that is used to shift data between TDi and TDO during data register scanning.

20.3 Test Data Register

As specified in IEEE 1149.1, the ZL50031 JTAG interface contains three test data registers:

- **The Boundary-Scan Register** - The Boundary-Scan register consists of a series of Boundary-Scan cells arranged to form a scan path around the boundary of the ZL50031 core logic.
- **The Bypass Register** - The Bypass register is a single stage shift register that provides a one-bit path from TDi to TDO.
- **The Device Identification Register** - The JTAG device ID for the ZL50031 is 0086614B_H.

0	0	0	0	0	0	0	0	BBPD2	BBPD1	BBPD0	LBPD2	LBPD1	LBPD0	BPE	0	0

Bit	Name	Description
15-9	Unused	Reserved. In normal functional mode, these bits MUST be set to zero.

Table 10 - Block Programming Mode (BPM) Register Bits

Bit	Name	Description
8-6	BBPD2-0	Backplane Block Programming Data Bits: These bits carry the value to be loaded into the backplane connection memory block whenever the Memory Block Programming feature is activated. After the MBP bit in the Control Register is set to high and the BPE is set to high, the contents of the bits BBPD2 - 0 are loaded into bits 15 - 13 of the backplane connection memory. Bits 12 - 0 of the backplane connection memory are programmed to be zero.
5-3	LBPD2-0	Local Block Programming Data Bits: These bits carry the value to be loaded into the local connection memory whenever the Memory Block Programming feature is activated. After the MBP bit in the Control Register is set to high and the BPE is set to high, the contents of the bits LBPD2 - 0 are loaded into bits 15 - 13 of the local connection memory. Bits 12 - 0 of the local connection memory are programmed to be zero.
2	BPE	Block Programming Enable: A low to high transition of this bit enables the Memory Block Programming function. The BPE, BBPD2-0 and LBPD2-0 in the BPM register must be defined in the same write operation. Once the BPE bit is set to high, ZL50031 requires two frames to complete the block programming. After the block programming has finished, the BPE bit returns to low to indicate that the operation is complete. When BPE is high, BPE or MBP can be set to low to abort the programming operation. When BPE is high, the other bits in the BPM register must not be changed for two frames to ensure proper operation. Whenever the microprocessor writes BPE to be high to start the block programming function, the user must maintain the same logical value on the other bits in the BPM register to avoid any change in the setting of the device.
1-0	Unused	Reserved. In normal functional mode, these bits MUST be set to zero.

Name	Description
LIDn4-0 (See Note 1)	Local Input Delay Bits 4 - 0: These five bits define how long the serial interface receiver takes to recognize and to store bit 0 from the LSTi _n input pins: i.e., to start a new frame. The input delay can be selected to +7 3/4 data rate clock periods from the frame boundary.
Note 1: n denotes an LSTi stream number from 0 to 15.	

Table 11 - Local Input Bit Delay Registers (LIDR0 to LIDR5) Bits

Local Input Bit Delay	Corresponding Delay Bits				
	LIDn4	LIDn3	LIDn2	LIDn1	LIDn0

Table 20 - DPLL Operation Mode (DOM2) Register Bits (continued)

	Bit	Primary Master Mode	Secondary Master Mode	Slave Mode
DOM1 Register Bits	BEN (bit 14)	0 - Monitor "B Clocks"	1 - Drive "B Clocks"	0 - Monitor "B Clocks"
	AEN (bit 13)	1 - Drive "A Clocks"	0 - Monitor "A Clocks"	0 - Monitor "A Clocks"
	RPS (bit 12)	0 - Preferred reference is PRI_REF	0 - Preferred reference is PRI_REF	0 - Preferred reference is PRI_REF
	FS1-0 (bits 11-10) Frequency of the secondary reference	00 - 8 kHz 01 - 1.544 MHz 10 - 2.048 MHz	00 - 8 kHz 01 - 1.544 MHz 10 - 2.048 MHz	11 - 8.192 MHz Clock ("B Clocks")
	FP1-0 (bits 9-8) Frequency of the primary reference	00 - 8 kHz 01 - 1.544 MHz 10 - 2.048 MHz	11 - 8.192 MHz Clock ("A Clocks")	11 - 8.192 MHz Clock ("A Clocks")
	SS3-0 (bits 7-4) Secondary reference selection:	0000 - CTREF1 0001 - CTREF2 1000 - LREF0 1001 - LREF1 1010 - LREF2 1011 - LREF3	0000 - CTREF1 0001 - CTREF2 1000 - LREF0 1001 - LREF1 1010 - LREF2 1011 - LREF3	XXXX - C8_B_io When bits FS1-0 are set to 11 , C8_B_io is always used as the secondary reference, regardless of the values of bits SS3-0. Output frame pulses are aligned to FRAME_B_io if secondary reference is the active reference
	SP3-0 (bits 3-0) Primary reference selection:	0000 - CTREF1 0001 - CTREF2 1000 - LREF0 1001 - LREF1 1010 - LREF2 1011 - LREF3	XXXX - C8_A_io When bits FP1-0 are set to 11 , C8_A_io is always used as the primary reference, regardless of the values of bits SP3-0. Output frame pulses are aligned to FRAME_A_io if primary reference is the active reference	XXXX - C8_A_io When bits FP1-0 are set to 11 , C8_A_io is always used as the primary reference, regardless of the values of bits SP3-0. Output frame pulses are aligned to FRAME_A_io if primary reference is the active reference
DOM2 Register Bits	MRST (bit 10)	0 - MTIE functional 1 - MTIE reset	0 - MTIE functional 1 - MTIE reset	1 - MTIE MUST be kept in the reset state in Slave mode
	FDM1, FDM0 (bits 9-8) Failure detect mode selection	00 - Autodetect Mode	00 - Autodetect Mode 01 - External Mode (Note 1)	00 - Autodetect Mode 01 - External Mode (Note 1)
* Note 1: It is assumed that the switching among references is done by external software control, if the External Mode is selected.				

Table 21 - ZL50031 Mode Selection - By Programming DOM1 and DOM2 Registers

Read/Write Address: 002D _H Reset Value: 0000 _H																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
POS 6	POS 5	POS 4	POS 3	POS 2	POS 1	POS 0	0	0	0	0	0	0	SKC2	SKC1	SKC0	

Bit	Name	Description
15 - 9	POS6 - 0	Phase Offset Bits: These seven bits refer to the 2's complement phase word to control the DPLL output phase offset. The offset varies in steps of 15 ns if the reference is 8 kHz or 2.048 MHz. The offset varies in steps of 20 ns if the reference is 1.544 MHz.
8 - 3	Unused	Reserved. In normal functional mode, these bits MUST be set to zero.
2 - 0	SKC2 - 0	Skew Control Bits: These three bits control the delay of the DPLL outputs from 0 to 7 steps in delay intervals of 3.5 ns.

Table 22 - DPLL Output Adjustment (DPOA) Register Bits

Read/Write Address: 002E _H for DHKR Register															
Reset Value: 0000 _H															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	SLS	PLS	CKM	Limit	State2	State1	State0

Bit	Name	Description
15 - 7	Unused	Reserved. In normal functional mode, these bits MUST be set to zero.
6	SLS	Secondary Loss Detection Bit (Read-only bit): When the secondary reference fails, this bit is set to high.
5	PLS	Primary Loss Detection Bit (Read-only bit): When the primary reference fails, this bit is set to high.
4	CKM	DPLL Output Clock Bit: When high, the primary output C32/64o is 65.536 MHz clock. When low, the primary output C32/64o is 32.768 MHz clock. This is the only writable bit in this register.
3	Limit	Limit (Read-only bit): Indicates that DPLL Phase Slope Limiter limits input phase.
2 - 0	State 2-0	State: These 3 bits indicate the state of the DPLL State Machine. Please refer to Figure 7, "State Machine Diagram" on page 25.

State 2-0	State Name
000	NORMAL_PRI
001	Reserved
010	HOLDOVER_PRI
011	MTIE_PRI
100	NORMAL_SEC
101	Reserved
110	HOLDOVER_SEC
111	MTIE_SEC

8 Mbps	LSTi0-15	LSAB3-0	LCAB6-0 (128-ch/frame)

Table 29 - LSAB and LCAB Bits Usage when Source Stream is from the Local Port

22.0 DC/AC Electrical Characteristics

Absolute Maximum Ratings*

	Parameter	Symbol	Min.	Max.	Units
1	Supply Voltage	V_{DD}	-0.5	5.0	V
2	BSTio Bias Voltage	V_{DD5V}	-0.5	7.0	V
3	Input Voltage	V_I	-0.5	$V_{DD} + 0.5$	V
4	Output Voltage	V_O	-0.5	$V_{DD} + 0.5$	V
5	Package power dissipation	P_D		2	W
6	Storage temperature	T_S	- 55	+125	°C

* Exceeding these values may cause permanent damage. Functional operation under these conditions is not implied.

Recommended Operating Conditions - Voltages are with respect to ground (V_{SS}) unless otherwise stated.

	Characteristics	Sym.	Min.	Typ. [‡]	Max.	Units
1	Operating Temperature	T_{OP}	-40	25	+85	°C
2	Positive Supply	V_{DD}	3.0	3.3	3.6	V
3	BSTio Bias Voltage (3 V PCI Spec)	V_{DD5V}	3.0	3.3	3.6	V
3	BSTio Bias Voltage (5 V PCI Spec)	V_{DD5V}	4.5	5.0	5.5	V
4	Input Voltage	V_I	0		V_{DD}	V
5	Input Voltage on 5 V Tolerant Inputs	V_{I_5V}	0		V_{DD5V}	V

‡ Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

DC Electrical Characteristics[†] - Voltages are with respect to ground (V_{SS}) unless otherwise stated.

	Characteristics	Sym.	Min.	Typ. [‡]	Max.	Units	Test Conditions
1	Supply Current	I_{DD}			480	mA	Outputs unloaded
2	Input High Voltage	V_{IH}	$0.7V_{DD}$			V	
3	Input Low Voltage	V_{IL}			$0.3V_{DD}$	V	
4	Input Leakage (input pins)	I_L			15	μA	$0 < V < V_{DD_IO}$ See Note 1
5	Weak Pullup Current	I_{PU}		33	50	μA	Input at 0V
6	Weak Pulldown Current	I_{PD}		33	50	μA	Input at V_{DD}
7	Input Pin Capacitance	C_I		5	10	pF	
8	Output High Voltage	V_{OH}	$0.8V_{DD}$			V	$I_{OH} = 10 \text{ mA}$
9	Output Low Voltage	V_{OL}			0.4	V	$I_{OL} = 10 \text{ mA}$
10	High Impedance Leakage	I_{OZ}			5	μA	$0 < V < V_{DD_IO}$
11	Output Pin Capacitance	C_O			15	pF	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

* Note 1: Maximum leakage on pins (output or I/O pins in high impedance state) is over an applied voltage (V_{in}).

AC Electrical Characteristics - Timing Parameter Measurement Voltage Levels

	Characteristics	Sym.	Level	Units	Conditions
1	CMOS Threshold	V_{CT}	$0.5V_{DD}$	V	
2	Rise/Fall Threshold Voltage High	V_{HM}	$0.7V_{DD}$	V	
3	Rise/Fall Threshold Voltage Low	V_{LM}	$0.3V_{DD}$	V	

AC Electrical Characteristics[†] - Input Frame Pulse and Input Clock Timing

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FRAME_A_io, FRAME_B_io Input Frame Pulse Width	t_{CFPIW}	90	122	180	ns	
2	FRAME_A_io, FRAME_B_io Input Frame Pulse Setup Time	t_{CFPIS}	45		90	ns	
3	FRAME_A_io, FRAME_B_io Input Frame Pulse Hold Time	t_{CFPIH}	45		90	ns	
4	C8_A_io, C8_B_io Input Clock Period	t_{C8MIP}	112	122	132	ns	
5	C8_A_io, C8_B_io Input Clock High Time	t_{C8MIH}	48		74	ns	
6	C8_A_io, C8_B_io Input Clock Low Time	t_{C8MIL}	48		74	ns	
7	C8_A_io, C8_B_io Input Rise/Fall Time	t_{rC8i}, t_{fC8i}	0		5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 15 - Backplane Frame Pulse Input and Clock Input Timing Diagram

AC Electrical Characteristics[†] - Output Frame Pulse and Output Clock Timing

AC Electrical Characteristics[†] - Local Frame Pulse and Clock Timing, $\overline{\text{ST_CKo}} = 4.096 \text{ MHz}$

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	Local Frame Boundary Offset ¹	t_{LFBOS}	6.5		25	ns	$C_L = 30 \text{ pF}$
2	$\overline{\text{ST_FPo0/1}}$ Width	t_{FPW4}	236.5	244	251.5	ns	
3	$\overline{\text{ST_FPo0/1}}$ Output Delay from Falling edge of $\overline{\text{ST_FPo0/1}}$ to falling edge of $\overline{\text{ST_CKo0/1}}$	t_{FODF4}	118.3		125.8	ns	
4	$\overline{\text{ST_FPo0/1}}$ Output Delay from Falling edge of $\overline{\text{ST_CKo0/1}}$ to rising edge of $\overline{\text{ST_FPo0/1}}$	t_{FODR4}	118.3		125.8	ns	
5	$\overline{\text{ST_CKo0/1}}$ Clock Period	t_{CP4}	236.5	244	251.5	ns	
6	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width High	t_{CH4}	118.3		125.8	ns	
7	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width Low	t_{CL4}	118.3		125.8	ns	
8	$\overline{\text{ST_CKo0/1}}$ Clock Rise/Fall Time	$t_{\text{rC4o}}, t_{\text{fC4o}}$			14	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Note 1: No jitter presented on input reference clock.

Figure 26 - Local Clock Timing Diagram when $\overline{\text{ST_CKo0/1}}$ frequency = 4.096 MHz

AC Electrical Characteristics[†] - Local Frame Pulse and Clock Timing, $\overline{\text{ST_CKo0}} = 8.192 \text{ MHz}$

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	Local Frame Boundary Offset ¹	t_{LFBOS}	6.5		25	ns	$C_L = 30 \text{ pF}$
2	$\overline{\text{ST_FPo0/1}}$ Width	t_{FPW8}	114.5	122	129.5	ns	
3	$\overline{\text{ST_FPo0/1}}$ Output Delay from Falling edge of $\overline{\text{ST_FPo0/1}}$ to falling edge of $\overline{\text{ST_CKo0/1}}$	t_{FODF8}	57.3		64.8	ns	
4	$\overline{\text{ST_FPo0/1}}$ Output Delay from Falling edge of $\overline{\text{ST_CKo0/1}}$ to rising edge of $\overline{\text{ST_FPo0/1}}$	t_{FODR8}	57.3		64.8	ns	
5	$\overline{\text{ST_CKo0/1}}$ Clock Period	t_{CP8}	114.5	122	129.5	ns	
6	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width High	t_{CH8}	57.3		64.8	ns	
7	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width Low	t_{CL8}	57.3		64.8	ns	
8	$\overline{\text{ST_CKo0/1}}$ Clock Rise/Fall Time	$t_{\text{rC8o}}, t_{\text{fC8o}}$			14	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only; not guaranteed and not subject to production testing.

Note 1: No jitter presented on input reference clock.

Figure 27 - Local Clock Timing Diagram when $\overline{\text{ST_CKo0/1}}$ frequency = 8.192 MHz

AC Electrical Characteristics[†] - Local Frame Pulse and Clock Timing, $\overline{\text{ST_CKo}} = 16.384 \text{ MHz}$

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	Local Frame Boundary Offset ¹	t_{LFBOS}	6.5		24.5	ns	$C_L = 30 \text{ pF}$
2	$\overline{\text{ST_FPo0/1}}$ Width	t_{FPW16}	53.5	61	68.5	ns	
3	$\overline{\text{ST_FPo0/1}}$ Output Setup from Falling edge of $\overline{\text{ST_FPo0/1}}$ to falling edge of $\overline{\text{ST_CKo0/1}}$	t_{FODF16}	26.8		34.3	ns	
4	$\overline{\text{ST_FPo}}$ Output Hold from Falling edge of $\overline{\text{ST_CKo0/1}}$ to rising edge of $\overline{\text{ST_FPo0/1}}$	t_{FODR16}	26.8		34.3	ns	
5	$\overline{\text{ST_CKo0/1}}$ Clock Period	t_{CP16}	53.5	61	68.5	ns	
6	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width High	t_{CH16}	26.8		34.3	ns	
7	$\overline{\text{ST_CKo0/1}}$ Clock Pulse Width Low	t_{CL16}	26.8		34.3	ns	
8	$\overline{\text{ST_CKo0/1}}$ Clock Rise/Fall Time	$t_{\text{rC16o}}, t_{\text{fC16o}}$			15	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Note 1: No jitter presented on input reference clock.

Figure 28 - Local Clock Timing Diagram when $\overline{\text{ST_CKo}}$ frequency = 16.384 MHz

AC Electrical Characteristics†- C1M5o Output Clock Timing

	Characteristic	Sym.	Min.	Typ.‡	Max.	Units	Notes
1	C1M5o Period	t_{C1M5oP}	640.5	648	655.5	ns	$C_L = 30$ pF
2	C1M5o High Time	t_{C1M5oH}	320.2	324	327.8	ns	
3	C1M5o Low Time	t_{C1M5oL}	320.2	324	327.8	ns	
4	C1M5o Rise Time	t_{rC1M5o}			10	ns	
5	C1M5o Fall Time	t_{fC1M5o}			11	ns	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 29 - C1M5o Output Clock Timing Diagram

AC Electrical Characteristics†- Output Clock Jitter Generation (Unfiltered)

	Characteristic	Typ.‡	Max.	Units	Notes
1	Jitter at C1M5o (1.544 MHz)	7.4	8.0	ns-pp	Device locks to 1.544 MHz reference input, and no jitter present on the reference
2	Jitter at $\overline{ST_CKo0-1}$ (4.096 MHz)	7.1	8.8	ns-pp	
3	Jitter at $\overline{ST_CKo0-1}$ (8.192 MHz)	7.0	8.3	ns-pp	
4	Jitter at $\overline{ST_CKo0-1}$ (16.384 MHz)	7.6	9.9	ns-pp	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - Backplane Serial Streams with Data Rate of 8 Mbps

	Characteristic	Sym.	Min. [‡]	Typ. [‡]	Max.	Units	Test Conditions
1	BSTio0-31 Input Data Sample Point	t_{SAMP8}	91.5	91.5	91.5	ns	
2	BSTio0-31 Input Setup Time	t_{CIS8}	12.5			ns	
3	BSTio0-31 Input Hold Time	t_{CIH8}	12.5			ns	
4	BSTio0-31 Output Delay Active to Active	t_{DOD8}	-6.5		12.5	ns	$C_L = 30$ pF, Note 1
5	Per Channel boundary HiZ	t_{DOZ8} t_{ZDO8}		10 10		ns ns	$R_L = 1$ K, $C_L = 30$ pF, Note 2

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

* Note 1: To meet the H.110 output timing requirement, the output delay time can be reduced further by programming the backplane output advancement registers (BOA0 - 3).

* Note 2: High Impedance is measured by pulling to the appropriate rail with R_L , with timing corrected to cancel the time taken to discharge C_L .

Figure 30 - Backplane Serial Stream Timing when the Data Rate is 8 Mbps

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Test Conditions
1	BSTio0-15 Input Data Sample Point	t _{SAMP16}	46	46	46	ns	
2	BSTio0-15 Input Setup Time	t _{CIS16}	12.5			ns	
3	BSTio0-15 Input Hold Time	t _{CIH16}	12.5			ns	
4	BSTio0-15 Output Delay Active to Active	t _{DOD16}	-6.5		12.5	ns	C _L = 30 pF

‡ Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - Local Serial Stream Output Timing

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Test Conditions
1	LSTo Delay - Active to Active						
	@2.048 Mbps	t_{SOD2}	-17.5		-6	ns	$C_L = 30 \text{ pF}$
	@4.096 Mbps	t_{SOD4}	-17.5		-6	ns	$C_L = 30 \text{ pF}$
	@8.192 Mbps	t_{SOD8}	-17.5		-6	ns	$C_L = 30 \text{ pF}$

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only; not guaranteed and not subject to production testing.

* See Section 7.0, "Local Output Timing Considerations" on page 15

Figure 32 - Local Serial Stream Output Timing

AC Electrical Characteristics[†] - Local Serial Stream Input Timing

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Test Conditions
1	LSTi Input Data Sample Point						
	@2.048 Mbps	t_{SAMP2L}	366	366	366	ns	
	@4.096 Mbps	t_{SAMP4L}	183	183	183	ns	
	@8.192 Mbps	t_{SAMP8L}	91.5	91.5	91.5	ns	
2	LSTi Setup Time
