Detailed Description

The SY88993AL is a high-sensitivity limiting post amplifier that operates from a single +3.3V power supply, over temperatures from -40°C to $+85^{\circ}\text{C}$. Signals with data rates up to 3.2Gbps and as small as 4mV_{PP} can be amplified. Figure 2 shows the allowed input voltage swing. The SY88993AL generates a LOS output. LOS_{LVL} sets the sensitivity of the input amplitude detection.

Input Amplifier/Buffer

Figure 3 shows a simplified schematic of the SY88993AL's input stage. The high-sensitivity of the input amplifier allows signals as small as 4mV_{PP} to be detected and amplified. The input amplifier also allows input signals as large as 1800mV_{PP}. Input signals below 6mV_{PP} are linearly amplified with a typical 38dB differential voltage gain. Since it is a limiting amplifier, the SY88993AL outputs typically 800mV_{PP} voltage-limited waveforms for input signals that are greater than 10mV_{PP}. Applications requiring the SY88993AL to operate with high-gain should have the upstream TIA placed as close as possible to the SY88993AL's input pins to ensure the best performance of the device.

Output Buffer

The SY88993AL's CML output buffer is designed to drive 50Ω lines. The output buffer requires appropriate termination for proper operation. An external 50Ω resistor to V_{CC} for each output pin provides this. Figure 4 shows a simplified schematic of the output stage.

Loss-of-Signal

The SY88993AL generates a chatter-free LOS open-collector TTL output which requires an external pull-up

resistor, as shown in Figure 1. LOS is used to determine that the input amplitude is large enough to be considered a valid input. LOS asserts high if the input amplitude falls below the threshold sets by LOS_{LVL} and de-asserts low otherwise. LOS can be fed back to the enable bar ($/EN$) input to maintain output stability under a loss of signal condition. $/EN$ de-asserts the true output signal without removing the input signals. Typically, 5.6dB LOS hysteresis is provided to prevent chattering.

Loss-of-Signal Level Set

The SY88993AL incorporates a programmable level detect function to identify when the input signal has been lost. This information can be fed back to the $/EN$ input of the device to maintain stability under loss of signal conditions. Using LOS_{LVL} pin the sensitivity of the level detect can be adjusted. The LOS_{LVL} voltage can be set by connection a resistor divider between V_{CC} and V_{REF} , Figure 5.

Hysteresis

The SY88993AL typically provides 5.6dB LOS electrical hysteresis. By definition, a power ratio measured in dB is $10\log(\text{power ratio})$. Power is calculated as V_{IN}^2/R for an electrical signal. Hence, the same ratio can be stated as $20\log(\text{voltage ratio})$. While in linear mode, the electrical voltage input changes linearly with the optical power and therefore, the ratios change linearly. Thus, the optical hysteresis in dB is half the electrical hysteresis in dB given in the data sheet. Since the SY88993AL is an electrical device, this data sheet refers to hysteresis in electrical terms. With 5.6dB LOS hysteresis, a voltage factor of about 2 is required to assert or de-assert LOS.

Notes:

1. Permanent device damage may occur if absolute maximum ratings are exceeded. This is a stress rating only and functional operation is not implied at conditions other than those detailed in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. The data sheet limits are not guaranteed if the device is operated beyond the operating ratings.
