TABLE OF CONTENTS

REVISION HISTORY

3/16—Rev. 0 to Rev. A

Changes to Figure 1 1
Change to Figure 17, Figure 18, and Figure 19 14
Changes to Figure 20 and Figure 21 14
Changes to Figure 40 and Figure 41 18
Changes to Power Supplies Section 20
Changes to Buffered Analog Input Section 27
Changes to Figure 65 Caption, Figure 66 Caption, and Figure 67 Caption 35
Changes to Figure 69 Caption 36
Changes to Delay Section 44

10/14—Revision 0: Initial Version

SPECIFICATIONS

AVDD1 = 3.0 V to 5.5 V, AVDD2 = IOVDD = 2 V to 5.5 V, AVSS = DGND = 0 V, REF+ = 2.5 V, REF− = AVSS, MCLK = internal master clock = 2 MHz, T_A = T_{MIN} to T_{MAX} (−40°C to +105°C), unless otherwise noted.

Table 1.

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
ADC SPEED AND PERFORMANCE					
Output Data Rate (ODR)		1.25		31,250	SPS
No Missing Codes[1]	Excluding sinc3 filter ≥ 15 kSPS	24			Bits
Resolution	See Table 6 and Table 7				
Noise	See Table 6 and Table 7				
ACCURACY					
Integral Nonlinearity (INL)			±2	±5	ppm of FSR
Offset Error[2]	Internal short		±40		µV
Offset Drift	Internal short		±65		nV/°C
Gain Error[2]	AVDD1 = 5 V		±5	±45	ppm of FSR
Gain Drift			±0.2	±0.5	ppm/°C
REJECTION					
Power Supply Rejection	AVDD1, AVDD2, V_{IN} = 1 V		98		dB
Common-Mode Rejection	V_{IN} = 0.1 V				
At DC		95			dB
At 50 Hz, 60 Hz[1]	20 Hz output data rate (postfilter), 50 Hz ± 1 Hz and 60 Hz ± 1 Hz	120			dB
Normal Mode Rejection[1]	50 Hz ± 1 Hz and 60 Hz ± 1 Hz				
	Internal clock, 20 SPS ODR (postfilter)	71	90		dB
	External clock, 20 SPS ODR (postfilter)	85	90		dB
ANALOG INPUTS					
Differential Input Range	V_{REF} = (REF+) − (REF−)		±V_{REF}		V
Absolute Voltage Limits[1]					
Input Buffers Disabled		AVSS − 0.05		AVDD1 + 0.05	V
Input Buffers Enabled		AVSS		AVDD1	V
Analog Input Current					
Input Buffers Disabled					
Input Current			±6		µA/V
Input Current Drift	External clock		±75		pA/V/°C
	Internal clock (±2.5% clock)		±0.5		nA/V/°C
Input Buffers Enabled					
Input Current			±5		nA
Input Current Drift			±0.1		nA/°C
Crosstalk	1 kHz input		−120		dB
INTERNAL REFERENCE	100 nF external capacitor to AVSS				
Output Voltage	REFOUT, with respect to AVSS		2.5		V
Initial Accuracy[3]	REFOUT, T_A = 25°C	−0.12		+0.12	% of V
Temperature Coefficient[1]					
0°C to 105°C			±2	±5	ppm/°C
−40°C to +105°C			±3	±10	ppm/°C
Reference Load Current, I_{LOAD}		−10		+10	mA
Power Supply Rejection	AVDD1, AVDD2 (line regulation)		90		dB
Load Regulation	$\Delta V_{OUT}/\Delta I_{LOAD}$		50		ppm/mA
Voltage Noise	e_N, 0.1 Hz to 10 Hz, 2.5 V reference		4.5		µV rms
Voltage Noise Density	e_N, 1 kHz, 2.5 V reference		215		nV/√Hz
Turn On Settling Time	100 nF REFOUT capacitor		200		µs
Short-Circuit Current, I_{SC}			25		mA

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
EXTERNAL REFERENCE INPUTS					
Differential Input Range	V_{REF} = (REF+) − (REF−)	1	2.5	AVDD1	V
Absolute Voltage Limits[1]					
Input Buffers Disabled		AVSS − 0.05		AVDD1 + 0.05	V
Input Buffers Enabled		AVSS		AVDD1	V
REFIN Input Current					
Input Buffers Disabled					
Input Current			±9		µA/V
Input Current Drift	External clock		±100		pA/V/°C
	Internal clock		±0.75		nA/V/°C
Input Buffers Enabled					
Input Current			±100		nA
Input Current Drift			±0.25		nA/°C
Normal Mode Rejection[1]	See the Rejection parameter				
Common-Mode Rejection			95		dB
TEMPERATURE SENSOR					
Accuracy	After user calibration at 25°C		±2		°C
Sensitivity			477		µV/K
BURNOUT CURRENTS					
Source/Sink Current	Analog input buffers must be enabled		±10		µA
GPIO (GPIO0, GPIO1)	With respect to AVSS				
Input Mode Leakage Current[1]		−10		+10	µA
Floating State Output Capacitance			5		pF
Output High Voltage, V_{OH}[1]	I_{SOURCE} = 200 µA	AVSS + 4			V
Output Low Voltage, V_{OL}[1]	I_{SINK} = 800 µA			AVSS + 0.4	V
Input High Voltage, V_{IH}[1]		AVSS + 3			V
Input Low Voltage, V_{IL}[1]				AVSS + 0.7	V
CLOCK					
Internal Clock					
Frequency			2		MHz
Accuracy		−2.5%		+2.5%	%
Duty Cycle			50		%
Output Low Voltage, V_{OL}				0.4	V
Output High Voltage, V_{OH}		0.8 × IOVDD			V
Crystal					
Frequency		14	16	16.384	MHz
Startup Time			10		µs
External Clock (CLKIO)			2	2.048	MHz
Duty Cycle[1]		30	50	70	%
LOGIC INPUTS					
Input High Voltage, V_{INH}[1]	2 V ≤ IOVDD < 2.3 V	0.65 × IOVDD			V
	2.3 V ≤ IOVDD ≤ 5.5 V	0.7 × IOVDD			V
Input Low Voltage, V_{INL}[1]	2 V ≤ IOVDD < 2.3 V			0.35 × IOVDD	V
	2.3 V ≤ IOVDD ≤ 5.5 V			0.7	V
Hysteresis[1]	IOVDD ≥ 2.7 V	0.08		0.25	V
	IOVDD < 2.7 V	0.04		0.2	V
Leakage Currents		−10		+10	µA

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
LOGIC OUTPUT (DOUT/$\overline{RDY}$)					
Output High Voltage, V_{OH}[1]	IOVDD ≥ 4.5 V, I_{SOURCE} = 1 mA	0.8 × IOVDD			V
	2.7 V ≤ IOVDD < 4.5 V, I_{SOURCE} = 500 µA	0.8 × IOVDD			V
	IOVDD < 2.7 V, I_{SOURCE} = 200 µA	0.8 × IOVDD			V
Output Low Voltage, V_{OL}[1]	IOVDD ≥ 4.5 V, I_{SINK} = 2 mA			0.4	V
	2.7 V ≤ IOVDD < 4.5 V, I_{SINK} = 1 mA			0.4	V
	IOVDD < 2.7 V, I_{SINK} = 400 µA			0.4	V
Leakage Current	Floating state	−10		+10	µA
Output Capacitance	Floating state		10		pF
SYSTEM CALIBRATION[1]					
Full-Scale (FS) Calibration Limit				1.05 × FS	V
Zero-Scale Calibration Limit		−1.05 × FS			V
Input Span		0.8 × FS		2.1 × FS	V
POWER REQUIREMENTS					
Power Supply Voltage					
AVDD1 to AVSS		3.0		5.5	V
AVDD2 to AVSS		2		5.5	V
AVSS to DGND		−2.75		0	V
IOVDD to DGND		2		5.5	V
IOVDD to AVSS	For AVSS < DGND			6.35	V
POWER SUPPLY CURRENTS[4]	All outputs unloaded, digital inputs connected to IOVDD or DGND				
Full Operating Mode					
AVDD1 Current					
AVDD1 = 5 V Typical, 5.5 V Maximum	AIN± and REF± buffers disabled; external reference		0.23	0.27	mA
	AIN± and REF± buffers disabled; internal reference		0.4	0.48	mA
	AIN± and REF± buffers enabled; internal reference		1.9	2.35	mA
	Each buffer: AIN± and REF±		0.38		mA
AVDD1 = 3.3 V Typical, 3.6 V Maximum[1]	AIN± and REF± buffers disabled; external reference		0.15	0.19	mA
	AIN± and REF± buffers disabled; internal reference		0.33	0.39	mA
	AIN± and REF± buffers enabled; internal reference		1.65	2.1	mA
	Each buffer: AIN± and REF±		0.33		mA
AVDD2 Current	External reference		1	1.1	mA
	Internal reference		1.3	1.45	mA
IOVDD Current	External clock		0.33	0.5	mA
	Internal clock		0.61	0.82	mA
	External crystal		0.98		mA
Standby Mode					
Standby (LDO On)	Reference off, total current consumption		32		µA
	Reference on, total current consumption		420		µA
Power-Down Mode	Full power-down, LDO, REF±		1	10	µA

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
POWER DISSIPATION[4]					
Full Operating Mode	Unbuffered, external clock and reference; AVDD1 = 3.3 V, AVDD2 = 2 V, IOVDD = 2 V		3.16		mW
	Unbuffered, external clock and reference; all supplies = 5 V		7.8		mW
	Unbuffered, external clock and reference; all supplies = 5.5 V			10.3	mW
	Fully buffered, internal clock and reference (note that REFOUT has no load); AVDD1 = 3.3 V, AVDD2 = 2 V, IOVDD = 2 V		9.27		mW
	Fully buffered, internal clock and reference (note that REFOUT has no load); all supplies = 5 V		19.1		mW
	Fully buffered, internal clock and reference (note that REFOUT has no load); all supplies = 5.5 V			25.4	mW
Standby Mode	Reference off, all supplies = 5 V		160		µW
	Reference on, all supplies = 5 V		2.1		mW
Power-Down Mode	Full power-down, all supplies = 5 V		5		µW
	Full power-down, all supplies = 5.5 V			55	µW

[1] This specification is not production tested but is supported by characterization data at initial product release.
[2] Following a system or internal zero-scale calibration, the offset error is in the order of the noise for the programmed output data rate selected. A system full-scale calibration reduces the gain error to the order of the noise for the programmed output data rate.
[3] This specification includes moisture sensitivity level (MSL) preconditioning effects.
[4] These specifications are with no load on the REFOUT and digital output pins.

TIMING CHARACTERISTICS

IOVDD = 2 V to 5.5 V, DGND = 0 V, Input Logic 0 = 0 V, Input Logic 1 = IOVDD, C_{LOAD} = 20 pF, unless otherwise noted.

Table 2.

Parameter	Limit at T_{MIN}, T_{MAX}	Unit	Test Conditions/Comments[1, 2]
SCLK			
t_3	25	ns min	SCLK high pulse width
t_4	25	ns min	SCLK low pulse width
READ OPERATION			
t_1	0	ns min	$\overline{CS}$ falling edge to DOUT/$\overline{RDY}$ active time
	15	ns max	IOVDD = 4.75 V to 5.5 V
	40	ns max	IOVDD = 2 V to 3.6 V
t_2[3]	0	ns min	SCLK active edge to data valid delay[4]
	12.5	ns max	IOVDD = 4.75 V to 5.5 V
	25	ns max	IOVDD = 2 V to 3.6 V
t_5	2.5	ns min	Bus relinquish time after $\overline{CS}$ inactive edge
	20	ns max	
t_6	0	ns min	SCLK inactive edge to $\overline{CS}$ inactive edge
t_7[5]	10	ns min	SCLK inactive edge to DOUT/$\overline{RDY}$ high/low
WRITE OPERATION			
t_8	0	ns min	$\overline{CS}$ falling edge to SCLK active edge setup time[4]
t_9	8	ns min	Data valid to SCLK edge setup time
t_{10}	8	ns min	Data valid to SCLK edge hold time
t_{11}	5	ns min	$\overline{CS}$ rising edge to SCLK edge hold time

[1] Sample tested during initial release to ensure compliance.
[2] See Figure 2 and Figure 3.
[3] This parameter is defined as the time required for the output to cross the V_{OL} or V_{OH} limits.
[4] The SCLK active edge is the falling edge of SCLK.
[5] DOUT/$\overline{RDY}$ returns high after a read of the data register. In single conversion mode and continuous conversion mode, the same data can be read again, if required, while DOUT/$\overline{RDY}$ is high, although care must be taken to ensure that subsequent reads do not occur close to the next output update. If the continuous read feature is enabled, the digital word can be read only once.

TIMING DIAGRAMS

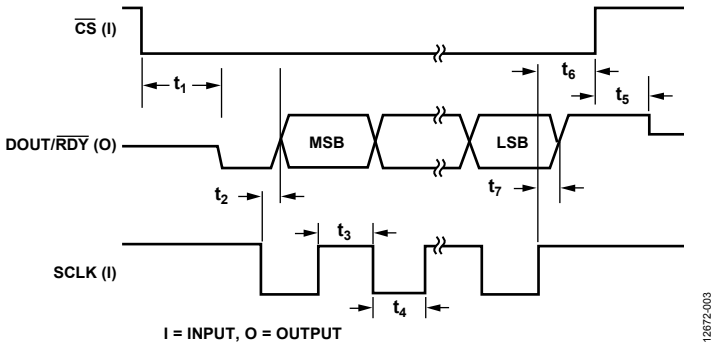

Figure 2. Read Cycle Timing Diagram

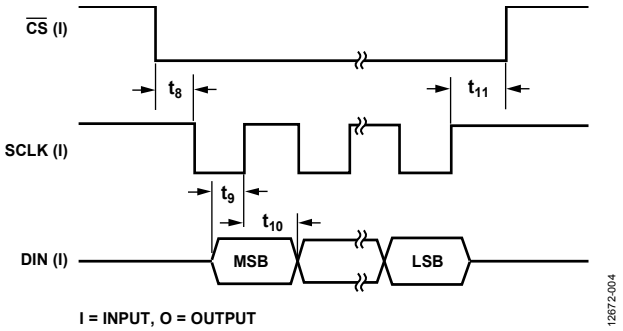

Figure 3. Write Cycle Timing Diagram

ABSOLUTE MAXIMUM RATINGS

T_A = 25°C, unless otherwise noted.

Table 3.

Parameter	Rating
AVDD1, AVDD2 to AVSS	−0.3 V to +6.5 V
AVDD1 to DGND	−0.3 V to +6.5 V
IOVDD to DGND	−0.3 V to +6.5 V
IOVDD to AVSS	−0.3 V to +7.5 V
AVSS to DGND	−3.25 V to +0.3 V
Analog Input Voltage to AVSS	−0.3 V to AVDD1 + 0.3 V
Reference Input Voltage to AVSS	−0.3 V to AVDD1 + 0.3 V
Digital Input Voltage to DGND	−0.3 V to IOVDD + 0.3 V
Digital Output Voltage to DGND	−0.3 V to IOVDD + 0.3 V
Analog Input/Digital Input Current	10 mA
Operating Temperature Range	−40°C to +105°C
Storage Temperature Range	−65°C to +150°C
Maximum Junction Temperature	150°C
Lead Soldering, Reflow Temperature	260°C
ESD Rating (HBM)	4 kV

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

θ_{JA} is specified for a device soldered on a JEDEC test board for surface-mount packages.

Table 4. Thermal Resistance

Package Type	θ_{JA}	Unit
24-Lead TSSOP		
1-Layer JEDEC Board	149	°C/W
2-Layer JEDEC Board	81	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

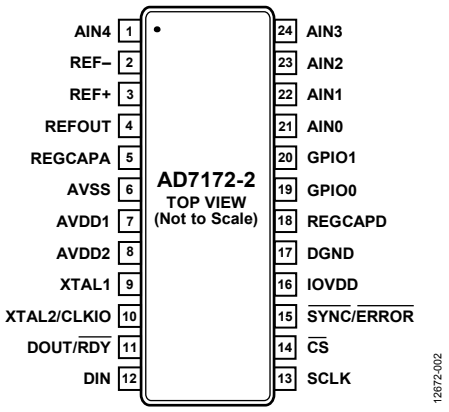

Figure 4. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Type[1]	Description
1	AIN4	AI	Analog Input 4. Analog Input 4 is selectable through the crosspoint multiplexer.
2	REF−	AI	Reference Input Negative Terminal. REF− can span from AVSS to AVDD1 − 1 V.
3	REF+	AI	Reference Input Positive Terminal. An external reference can be applied between REF+ and REF−. REF+ can span from AVSS + 1 V to AVDD1.The device functions with a reference magnitude from 1 V to AVDD1.
4	REFOUT	AO	Buffered Output of Internal Reference. The output is 2.5 V with respect to AVSS.
5	REGCAPA	AO	Analog LDO Regulator Output. Decouple this pin to AVSS using a 1 µF and a 0.1 µF capacitor.
6	AVSS	P	Negative Analog Supply. This supply ranges from −2.75 V to 0 V and is nominally set to 0 V.
7	AVDD1	P	Analog Supply Voltage 1. This voltage is 3.3 V or 5 V ± 10% with respect to AVSS.
8	AVDD2	P	Analog Supply Voltage 2. This voltage ranges from 2 V to 5.5 V with respect to AVSS.
9	XTAL1	AI	Input 1 for Crystal.
10	XTAL2/CLKIO	AI/ DI/O	Input 2 for Crystal/Clock Input or Output. Based on the CLOCKSEL bits in the ADCMODE register. The following four options are available for selecting the MCLK source: Internal oscillator: no output. Internal oscillator: output to XTAL2/CLKIO. Operates at IOVDD logic level. External clock: input to XTAL2/CLKIO. Input must be at IOVDD logic level. External crystal: connected between XTAL1 and XTAL2/CLKIO.
11	DOUT/$\overline{\text{RDY}}$	DO	Serial Data Output/Data Ready Output. DOUT/$\overline{\text{RDY}}$ is a dual purpose pin. This pin functions as a serial data output pin to access the output shift register of the ADC. The output shift register can contain data from any of the on-chip data or control registers. The data-word/control word information is placed on the DOUT/$\overline{\text{RDY}}$ pin on the SCLK falling edge and is valid on the SCLK rising edge. When $\overline{\text{CS}}$ is high, the DOUT/$\overline{\text{RDY}}$ output is three-stated. When $\overline{\text{CS}}$ is low, DOUT/$\overline{\text{RDY}}$ operates as a data ready pin, going low to indicate the completion of a conversion. If the data is not read after the conversion, the pin goes high before the next update occurs. The DOUT/$\overline{\text{RDY}}$ falling edge can be used as an interrupt to a processor, indicating that valid data is available.
12	DIN	DI	Serial Data Input to the Input Shift Register on the ADC. Data in this shift register is transferred to the control registers in the ADC, with the register address (RA) bits of the communications register identifying the appropriate register. Data is clocked in on the rising edge of SCLK.
13	SCLK	DI	Serial Clock Input. This serial clock input is for data transfers to and from the ADC. The SCLK has a Schmitt triggered input, making the interface suitable for opto-isolated applications.
14	$\overline{\text{CS}}$	DI	Chip Select Input. This is an active low logic input selects the ADC. $\overline{\text{CS}}$ can select the ADC in systems with more than one device on the serial bus. $\overline{\text{CS}}$ can be hardwired low, allowing the ADC to operate in 3-wire mode with the SCLK, DIN, and DOUT pins interfacing with the device. When $\overline{\text{CS}}$ is high, the DOUT/$\overline{\text{RDY}}$ output is three-stated.

Pin No.	Mnemonic	Type[1]	Description
15	$\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$	DI/O	Synchronization Input/Error Input/Output. This pin can be switched between a logic input and a logic output in the GPIOCON register. When synchronization input ($\overline{\text{SYNC}}$) is enabled, this pin allows synchronization of the digital filters and analog modulators when using multiple AD7172-2 devices. For more information, see the Synchronization section. When the synchronization input is disabled, this pin can be used in one of the following three modes: Active low error input mode: this mode sets the ADC_ERROR bit in the status register. Active low, open-drain error output mode: the status register error bits are mapped to the $\overline{\text{ERROR}}$ output. The $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ pins of multiple devices can be wired together to a common pull-up resistor so that an error on any device can be observed. General-purpose output mode: the status of the pin is controlled by the ERR_DAT bit in the GPIOCON register. The pin is referenced between IOVDD and DGND, as opposed to the AVDD1 and AVSS levels used by the GPIOx pins. The pin has an active pull-up in this case.
16	IOVDD	P	Digital Input/Output Supply Voltage. The IOVDD voltage ranges from 2 V to 5.5 V. IOVDD is independent of AVDD2. For example, IOVDD can be operated at 3 V when AVDD2 equals 5 V, or vice versa. If AVSS is set to −2.5 V, the voltage on IOVDD must not exceed 3.6 V.
17	DGND	P	Digital Ground.
18	REGCAPD	AO	Digital LDO Regulator Output. This pin is for decoupling purposes only. Decouple this pin to DGND using a 1 µF and a 0.1 µF capacitor.
19	GPIO0	DI/O	General-Purpose Input/Output 0. The pin is referenced between the AVDD1 and AVSS levels.
20	GPIO1	DI/O	General-Purpose Input/Output 1. The pin is referenced between the AVDD1 and AVSS levels.
21	AIN0	AI	Analog Input 0. Analog Input 0 is selectable through the crosspoint multiplexer.
22	AIN1	AI	Analog Input 1. Analog Input1 is selectable through the crosspoint multiplexer.
23	AIN2	AI	Analog Input 2. Analog Input 2 is selectable through the crosspoint multiplexer.
24	AIN3	AI	Analog Input 3. Analog Input 3 is selectable through the crosspoint multiplexer.

[1] AI is analog input, AO is analog output, DI/O is bidirectional digital input/output, DO is digital output, DI is digital input, and P is power supply.

TYPICAL PERFORMANCE CHARACTERISTICS

AVDD1 = 5 V, AVDD2 = 5 V, IOVDD = 3.3 V, T_A = 25°C, unless otherwise noted.

NOISE PERFORMANCE AND RESOLUTION

Table 6 and Table 7 show the rms noise, peak-to-peak noise, effective resolution, and the noise free (peak-to-peak) resolution of the AD7172-2 for various output data rates and filters. The numbers given are for the bipolar input range with an external 5 V reference. These numbers are typical and are generated with a differential input voltage of 0 V when the ADC is continuously converting on a single channel. It is important to note that the peak-to-peak resolution is calculated based on the peak-to-peak noise. The peak-to-peak resolution represents the resolution for which there is no code flicker.

Table 6. RMS Noise and Peak-to-Peak Resolution vs. Output Data Rate Using Sinc5 + Sinc1 Filter (Default)[1]

Output Data Rate (SPS)	RMS Noise (μV rms)	Effective Resolution (Bits)	Peak-to-Peak Noise (μV p-p)	Peak-to-Peak Resolution (Bits)
Input Buffers Disabled				
31,250	8.2	20.2	66	17.2
15,625	7.0	20.4	52	17.5
10,417	6.0	20.7	45	17.8
1007	2.2	22.2	15	19.3
59.52	0.48	24	3.2	21.6
49.68	0.47	24	3.1	21.6
16.63	0.25	24	1.6	22.6
1.25	0.088	24	0.32	24
Input Buffers Enabled				
31,250	9.5	20	74	17
15,625	8.2	20.2	63	17.3
10,417	7.1	20.4	53	17.5
1007	2.6	21.9	16	19.3
59.52	0.62	24	3.6	21.4
49.68	0.53	24	3.3	21.5
16.63	0.32	24	1.7	22.2
1.25	0.089	24	0.35	24

[1] Selected rates only, 1000 samples.

Table 7. RMS Noise and Peak-to-Peak Resolution vs. Output Data Rate Using Sinc3 Filter[1]

Output Data Rate (SPS)	RMS Noise (μV rms)	Effective Resolution (Bits)	Peak-to-Peak Noise (μV p-p)	Peak-to-Peak Resolution (Bits)
Input Buffers Disabled

GETTING STARTED

The AD7172-2 offers the user a fast settling, high resolution, multiplexed ADC with high levels of configurability, including the following features:

- Two fully differential or four single-ended analog inputs.
- A crosspoint multiplexer selects any analog input combination as the input signals to be converted, routing them to the modulator positive or negative input.
- True rail-to-rail buffered analog and reference inputs.
- Fully differential input or single-ended input relative to any analog input.
- Per channel configurability—up to four different setups can be defined. A separate setup can be mapped to each of the channels. Each setup allows the user to configure whether the buffers are enabled or disabled, gain and offset correction, filter type, output data rate, and reference source selection (internal or external).

The AD7172-2 includes a precision, 2.5 V, low drift (±2 ppm/°C) band gap internal reference. This reference can be used for the ADC conversions, reducing the external component count. Alternatively, the reference can be output to the REFOUT pin to be used as a low noise biasing voltage for external circuitry. An example of this is using the REFOUT signal to set the input common mode for an external amplifier.

The AD7172-2 includes two separate linear regulator blocks for both the analog and digital circuitry. The analog LDO regulator regulates the AVDD2 supply to 1.8 V, supplying the ADC core. The user can tie the AVDD1 and AVDD2 supplies together for easiest connection. If there is already a clean analog supply rail in the system in the range of 2 V (minimum) to 5.5 V (maximum), the user can also choose to connect this supply to the AVDD2 input, allowing lower power dissipation.

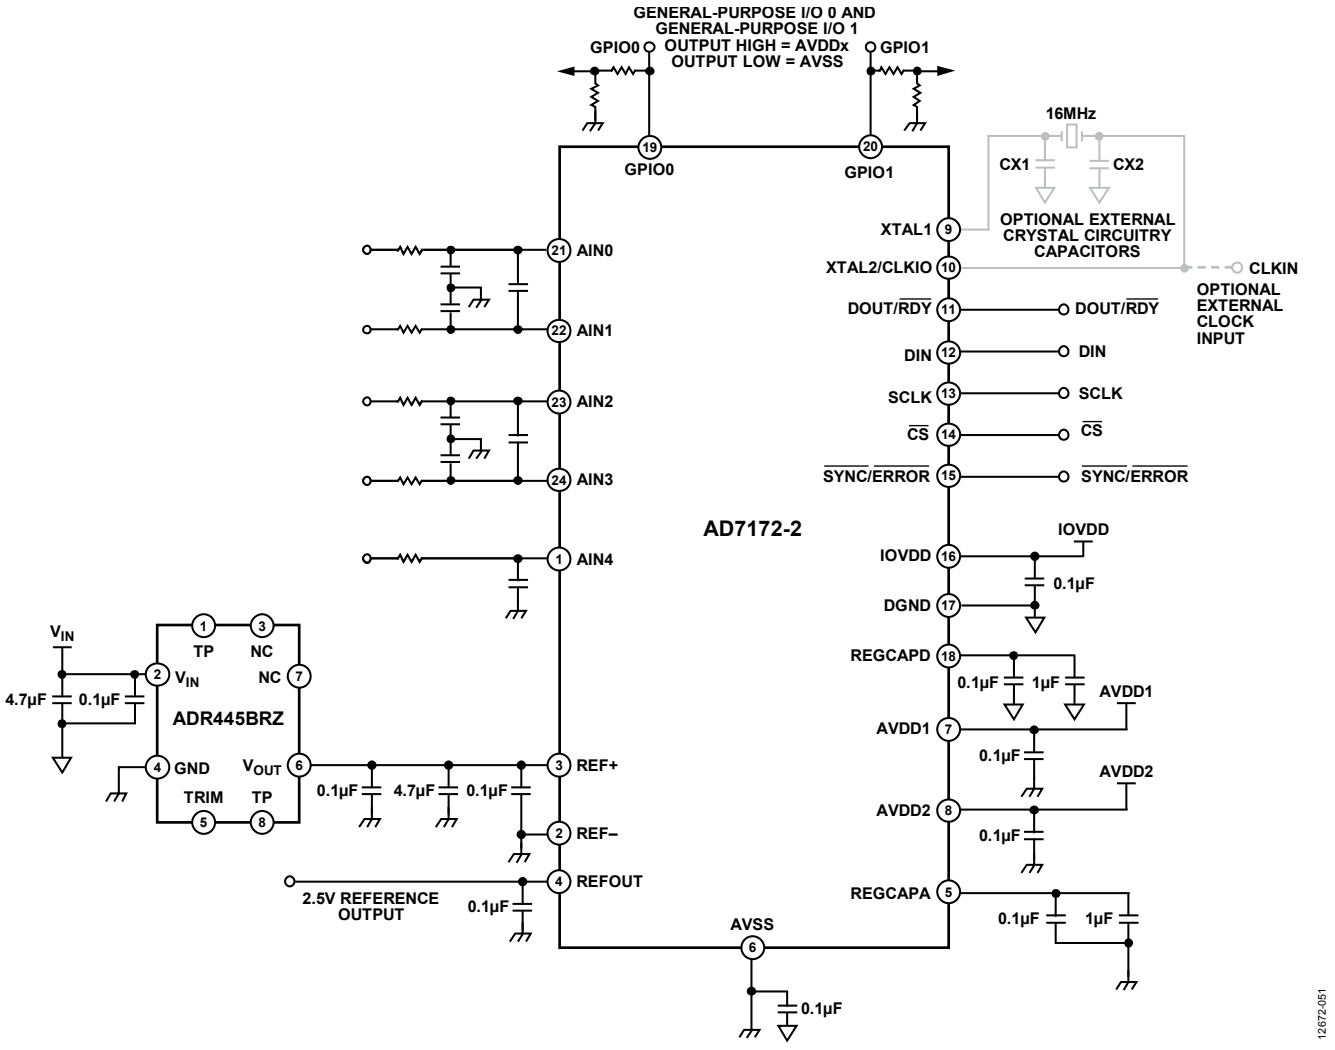

Figure 42. Typical Connection Diagram

The linear regulator for the digital IOVDD supply regulates the input voltage applied at the IOVDD pin to 1.8 V for the internal digital filtering. The serial interface signals always operate from the IOVDD supply seen at the pin; if 3.3 V is applied to the IOVDD pin, the interface logic inputs and outputs operate at this level.

The AD7172-2 can be used across a wide variety of applications, providing high resolution and accuracy. A sample of these scenarios is as follows:

- Fast scanning of analog input channels using the internal multiplexer
- Fast scanning of analog input channels using an external multiplexer with automatic control from the GPIOs
- High resolution at lower speeds in either channel scanning or ADC per channel applications
- Single ADC per channel: the fast low latency output allows further application specific filtering in an external microcontroller, DSP, or field programmable gate array (FPGA)

POWER SUPPLIES

The AD7172-2 has three independent power supply pins: AVDD1, AVDD2, and IOVDD. AVDD1 powers the crosspoint multiplexer and integrated analog and reference input buffers. AVDD1 is referenced to AVSS, and AVDD1 − AVSS = 3.3 V or 5 V. AVDD1 and AVSS can be a single 3.3 V or 5 V supply or a ±1.65 V or ±2.5 V split supply. The split supply operation allows true bipolar inputs. When using split supplies, consider the absolute maximum ratings (see the Absolute Maximum Ratings section).

AVDD2 powers the internal 1.8 V analog LDO regulator. This regulator powers the ADC core. AVDD2 is referenced to AVSS, and AVDD2 to AVSS can range from 5.5 V (maximum) to 2 V (minimum).

IOVDD powers the internal 1.8 V digital LDO regulator. This regulator powers the digital logic of the ADC. IOVDD sets the voltage levels for the SPI interface of the ADC. IOVDD is referenced to DGND, and IOVDD to DGND can vary from 5.5 V (maximum) to 2 V (minimum).

There is no specific requirement for a power supply sequence on the AD7172-2. When all power supplies are stable, a device reset is required; see the AD7172-2 Reset section for details on how to reset the device.

Recommended Linear Regulators

The ADP7118 provides positive supply rails to the AD7172-2, creating either a single 5 V, 3.3 V, or dual AVDD1/IOVDD, depending on the required supply configuration. The ADP7118 can operate from input voltages up to 20 V.

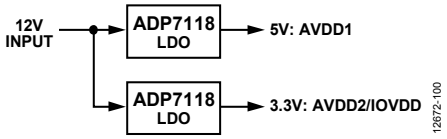

Figure 43. Single Supply Linear Regulator

The ADM660 and ADP7182 generate a clean negative rail for AVSS in the bipolar configuration to provide optimal converter performance.

ADP7182	−28 V, −200 mA, low noise, linear regulator
ADM660	CMOS switched-capacitor voltage converter

DIGITAL COMMUNICATION

The AD7172-2 has a 3- or 4-wire SPI interface that is compatible with QSPI™, MICROWIRE, and DSPs. The interface operates in SPI Mode 3 and can be operated with $\overline{CS}$ tied low. In SPI Mode 3, the SCLK idles high, the falling edge of SCLK is the drive edge, and the rising edge of SCLK is the sample edge. This means that data is clocked out on the falling/drive edge and data is clocked in on the rising/sample edge.

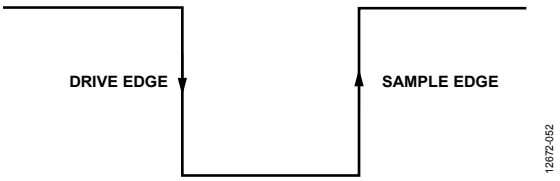

Figure 45. SPI Mode 3 SCLK Edges

Accessing the ADC Register Map

The communications register controls access to the full register map of the ADC. This register is an 8-bit write only register. On power-up or after a reset, the digital interface defaults to a state where it is expecting a write to the communications register; therefore, all communication begins by writing to the communications register.

The data written to the communications register determines which register is being accessed and if the next operation is a read or write. The register address bits (RA, Bits[5:0] in Register 0x00) determine the specific register to which the read or write operation applies.

When the read or write operation to the selected register is complete, the interface returns to the default state, where it expects a write operation to the communications register.

Figure 46 and Figure 47 illustrate writing to and reading from a register by first writing the 8-bit command to the communications register, followed by the data for that register.

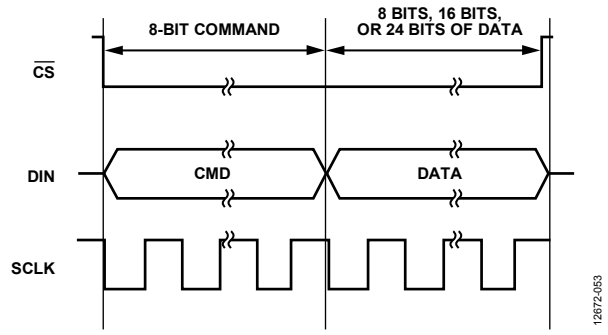

Figure 46. Writing to a Register (8-Bit Command with Register Address Followed by Data of 8, 16, or 24 Bits; Data Length on DIN Is Dependent on the Register Selected)

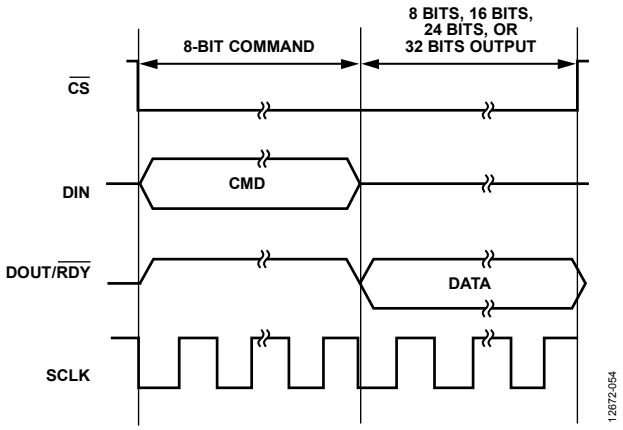

Figure 47. Reading from a Register (8-Bit Command with Register Address Followed by Data of 8, 16, or 24 Bits; Data Length on DOUT/RDY Is Dependent on the Register Selected)

Reading the ID register is the recommended method for verifying correct communication with the device. The ID register is a read only register and contains the value 0x00DX for the AD7172-2. The communications register and the ID register details are described in Table 9 and Table 10.

AD7172-2 RESET

After a power-up cycle and when the power supplies are stable, a device reset is required. In situations where interface synchronization is lost, a device reset is also required. A write operation of at least 64 serial clock cycles with DIN high returns the ADC to the default state by resetting the entire device, including the register contents. Alternatively, if $\overline{CS}$ is being used with the digital interface, returning $\overline{CS}$ high sets the digital interface to the default state and halts any serial interface operation.

CONFIGURATION OVERVIEW

After power-on or reset, the AD7172-2 default configuration is as follows:

- Channel configuration: CH0 is enabled, AIN0 is selected as the positive input, and AIN1 is selected as the negative input. Setup 0 is selected.
- Setup configuration: The internal reference and the analog input buffers are disabled. The reference input buffers are also disabled. An external reference on the REF± pins is selected.
- Filter configuration: The sinc5 + sinc1 filter is selected and the maximum output data rate of 31.25 kSPS is selected.
- ADC mode: Continuous conversion mode and the internal oscillator are enabled.
- Interface mode: CRC and data + status output are disabled.

Note that only a few of the register setting options are shown; this list is just an example. For full register information, see the Register Details section.

Figure 48 shows an overview of the suggested flow for changing the ADC configuration, divided into the following three blocks:

- Channel configuration (see Box A in Figure 48)
- Setup configuration (see Box B in Figure 48)
- ADC mode and interface mode configuration (see Box C in Figure 48)

Channel Configuration

The AD7172-2 has four independent channels and four independent setups. The user can select any of the analog input pairs on any channel, as well as any of the four setups for any channel, giving the user full flexibility in the channel configuration. This also allows per channel configuration when using differential inputs and single-ended inputs because each channel can have a dedicated setup.

Channel Registers

The channel registers select which of the five analog input pins (AIN0 to AIN4) are used as either the positive analog input (AIN+) or the negative analog input (AIN−) for that channel. This register also contains a channel enable/disable bit and the setup selection bits, which select which of the four available setups to use for this channel.

When the AD7172-2 is operating with more than one channel enabled, the channel sequencer cycles through the enabled channels in sequential order, from Channel 0 to Channel 3. If a channel is disabled, it is skipped by the sequencer. Details of the channel register for Channel 0 are shown in Table 11.

ADC Setups

The AD7172-2 has four independent setups. Each setup consists of the following four registers:

- Setup configuration register
- Filter configuration register
- Gain register
- Offset register

For example, Setup 0 consists of Setup Configuration Register 0, Filter Configuration Register 0, Gain Register 0, and Offset Register 0. Figure 49 shows the grouping of these registers. The setup is selectable from the channel registers (see the Channel Configuration section), which allows each channel to be assigned to one of four separate setups. Table 12 through Table 15 show the four registers that are associated with Setup 0. This structure is repeated for Setup 1 to Setup 3.

Setup Configuration Registers

The setup configuration registers allow the user to select the output coding of the ADC by selecting between bipolar mode and unipolar mode. In bipolar mode, the ADC accepts negative differential input voltages, and the output coding is offset binary. In unipolar mode, the ADC accepts only positive differential voltages, and the coding is straight binary. In either case, the input voltage must be within the AVDD1/AVSS supply voltages. The user can select the reference source using these registers. Three options are available: an internal 2.5 V reference, an external reference connected between the REF+ and REF– pins, or AVDD1 – AVSS. The analog input and reference input buffers can also be enabled or disabled using these registers.

Filter Configuration Registers

The filter configuration registers select which digital filter is used at the output of the ADC modulator. The order of the filter and the output data rate is selected by setting the bits in these registers. For more information, see the Digital Filters section.

Reg.	Name	Bits	Bits[23:0]	Reset	RW
0x30	OFFSET0	[23:0]	OFFSET0[23:0]	0x800000	RW

Gain Registers

The gain registers are 24-bit registers that hold the gain calibration coefficient for the ADC. The gain registers are read/write registers. These registers are configured at power-on with factory calibrated coefficients. Therefore, every device has different default coefficients. The default value is automatically overwritten if the user initiates a system full-scale calibration or writes to a gain register. For more information on calibration, see the Operating Modes section.

Offset Registers

The offset registers hold the offset calibration coefficient for the ADC. The power-on reset value of the offset registers is 0x800000. The offset registers are 24-bit read/write registers. The power-on reset value is automatically overwritten if the user initiates an internal or system zero-scale calibration or if the user writes to an offset register.

ADC Mode and Interface Mode Configuration

The ADC mode register and the interface mode register configure the core peripherals for use by the AD7172-2 and the mode for the digital interface.

ADC Mode Register

The ADC mode register primarily sets the conversion mode of the ADC to either continuous or single conversion. The user can also select the standby and power-down modes, as well as any of the calibration modes. In addition, this register contains the clock source select bits and the internal reference enable bits. The reference select bits are contained in the setup configuration registers (see the ADC Setups section for more information). The details of this register are shown in Table 16.

Interface Mode Register

The interface mode register configures the digital interface operation. This register allows the user to control data-word length, CRC enable, data plus status read, and continuous read mode. The details of this register are shown in Table 17. For more information, see the Digital Interface section.

Understanding Configuration Flexibility

The most straightforward implementation of the AD7172-2 is to use two differential inputs with adjacent analog inputs and run both of them with the same setup, gain correction, and offset correction register. In this case, the user selects the following differential inputs: AIN0/AIN1 and AIN2/AIN3. In Figure 50, the registers shown in black font must be programmed for such a configuration. The registers that are shown in gray font are redundant in this configuration.

Programming the gain and offset registers is optional for any use case, as indicated by the dashed lines between the register blocks.

An alternative way to implement these two fully differential inputs is to take advantage of the four available setups. Motivation for doing this includes having a different speed/noise requirement on each of the differential inputs, or there may be a specific offset or gain correction for each channel. Figure 51 shows how each of the differential inputs can use a separate setup, allowing full flexibility in the configuration of each channel.

Figure 52 shows an example of how the channel registers span between the analog input pins and the setup configurations downstream. In this example, one differential input and two single-ended inputs are required. The single-ended inputs are the AIN2/AIN4 and AIN3/AIN4 combinations. The differential input pair is AIN0/AIN1 and uses Setup 0. The two single-ended input pairs are set up as diagnostics; therefore, they use a separate setup from the differential input but share a setup between them, Setup 1. Given that two setups are selected, SETUPCON0 and SETUPCON1 are programmed as required, and FILTCON0 and FILTCON1 are programmed as desired. Optional gain and offset correction can be employed on a per setup basis by programming GAIN0 and GAIN1 and OFFSET0 and OFFSET1.

In the example shown in Figure 52, the CH0 to CH2 registers are used. Setting the MSB in each of these registers, the CH_EN0 to CH_EN2 bits enable the three combinations via the crosspoint mux. When the AD7172-2 converts, the sequencer transitions in ascending sequential order from CH0 to CH1 to CH2 before looping back to CH0 to repeat the sequence.

CIRCUIT DESCRIPTION

BUFFERED ANALOG INPUT

The AD7172-2 has true rail-to-rail, integrated, precision unity gain buffers on both ADC analog inputs. The buffers provide high input impedance with only 5 nA typical input current, allowing high impedance sources connect directly to the analog inputs. The buffers fully drive the internal ADC switch capacitor sampling network, simplifying the analog front-end circuit requirements while consuming a very efficient 0.38 mA typical per buffer. Each analog input buffer amplifier is fully chopped, meaning that it minimizes the offset error drift and 1/f noise of the buffer. The 1/f noise profile of the ADC and buffer combined is shown in Figure 53.

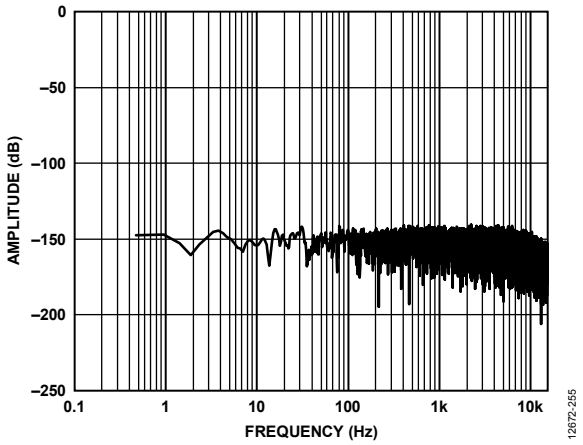

Figure 53. Shorted Input FFT (Analog Input Buffers Enabled)

The analog input buffers do not suffer from linearity degradation when operating at the rails, unlike many discrete amplifiers. When operating at or close to the AVDD1 and AVSS supply rails, there is an increase in input current. This increase is most notable at higher temperatures. Figure 40 and Figure 41 show the input current for various conditions. With the analog input buffers disabled, the average input current to the AD7172-2 changes linearly with the differential input voltage at a rate of 6 µA/V.

CROSSPOINT MULTIPLEXER

There are five analog input pins: AIN0, AIN1, AIN2, AIN3, and AIN4. Each of these pins connects to the internal crosspoint multiplexer. The crosspoint multiplexer enables any of these inputs to be configured as an input pair, either single-ended or fully differential. The AD7172-2 can have up to four active channels. When more than one channel is enabled, the channels are automatically sequenced in order from the lowest enabled channel number to the highest enabled channel number. The output of the multiplexer is connected to the input of the integrated true rail-to-rail buffers. These buffers can be bypassed and the multiplexer output can directly connect to the switched-capacitor input of the ADC. The simplified analog input circuit is shown in Figure 54.

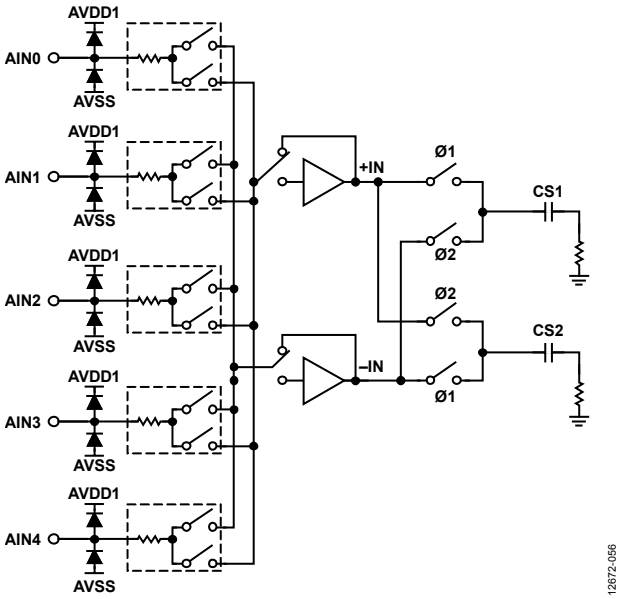

Figure 54. Simplified Analog Input Circuit

The CS1 and CS2 capacitors have a magnitude in the order of a number of picofarads each. This capacitance is the combination of both the sampling capacitance and the parasitic capacitance.

Fully Differential Inputs

Because the AIN0 to AIN4 analog inputs are connected to a crosspoint multiplexer, any combination of signals can create an analog input pair. This allows the user to select two fully differential inputs or four single-ended inputs.

If two fully differential input paths are connected to the AD7172-2, using AIN0/AIN1 as one differential input pair and AIN2/AIN3 as the second differential input pair is recommended. This is due to the relative locations of these pins to each other. Decouple all analog inputs to AVSS.

Single-Ended Inputs

The user can also choose to measure four different single-ended analog inputs. In this case, each of the analog inputs is converted as the difference between the single-ended input to be measured and a set analog input common pin. Because there is a crosspoint multiplexer, the user can set any of the analog inputs as the common pin. An example of such a scenario is to connect the AIN4 pin to AVSS or to the REFOUT voltage (that is, AVSS + 2.5 V) and select this input when configuring the crosspoint multiplexer. When using the AD7172-2 with single-ended inputs, the INL specification is degraded.

AD7172-2 REFERENCE

The AD7172-2 offers the user the option of either supplying an external reference to the REF+ and REF− pins of the device or allowing the use of the internal 2.5 V, low noise, low drift reference. Select the reference source to be used by the analog input by setting the REF_SELx bits (Bits[5:4]) in the setup configuration registers appropriately. The structure of the Setup Configuration 0 register is shown in Table 18. The AD7172-2 defaults on power-up to use the external reference inputs, REF+ and REF−.

External Reference

The AD7172-2 has a fully differential reference input applied through the REF+ and REF− pins. Standard low noise, low drift voltage references, such as the ADR445, ADR444, and ADR441, are recommended for use. Apply the external reference to the AD7172-2 reference pins as shown in Figure 55. Decouple the output of any external reference to AVSS. As shown in Figure 55, the ADR445 output is decoupled with a 0.1 µF capacitor at the output for stability purposes. The output is then connected to a 4.7 µF capacitor, which acts as a reservoir for any dynamic charge required by the ADC, and followed by a 0.1 µF decoupling capacitor at the REF+ input. This capacitor is placed as close as possible to the REF+ and REF− pins.

The REF− pin is connected directly to the AVSS potential. On power-up of the AD7172-2, the internal reference is disabled by default. The external reference is used by default instead of the internal reference. When an external reference is used instead of the internal reference to supply the AD7172-2, attention must be paid to the output of the REFOUT pin. If the internal reference is not being used elsewhere in the application, ensure that the REFOUT pin is not hardwired to AVSS because this draws a large current on power-up. The internal reference is controlled by the REF_EN bit (Bit 15) in the ADC mode register, which is shown in Table 19.

Internal Reference

The AD7172-2 includes a low noise, low drift voltage reference. The internal reference has a 2.5 V output. The internal reference is output on the REFOUT pin after the REF_EN bit in the ADC mode register is set and is decoupled to AVSS with a 0.1 µF capacitor. The AD7172-2 internal reference is disabled by default on power-up.

The REFOUT signal is buffered before being output to the pin. The signal can be used externally in the circuit as a common-mode source for external amplifier configurations.

		[7:0]	Reserved	Mode		CLOCKSEL		Reserved				

BUFFERED REFERENCE INPUT

The AD7172-2 has true rail-to-rail, integrated, precision unity-gain buffers on both ADC reference inputs. The buffers provide the benefit of providing high input impedance and allowing high impedance external sources to be directly connected to the reference inputs. The integrated reference buffers can fully drive the internal reference switch capacitor sampling network, simplifying the reference circuit requirements while consuming a very efficient 0.38 mA typical per buffer. Each reference input buffer amplifier is fully chopped, meaning that it minimizes the offset error drift and 1/f noise of the buffer. When using an external reference, such as the ADR445, ADR444, or ADR441, these buffers are not required because these references, with proper decoupling, can drive the reference inputs directly.

CLOCK SOURCE

The AD7172-2 uses a nominal master clock of 2 MHz. The AD7172-2 can source the sampling clock from one of three sources:

- Internal oscillator
- External crystal (use a 16 MHz crystal, automatically divided internally to set the 2 MHz clock)
- External clock source

All output data rates listed in the data sheet relate to a master clock rate of 2 MHz. Using a lower clock frequency from, for instance, an external source scales any listed data rate proportionally. To achieve the specified data rates, particularly rates for rejection of 50 Hz and 60 Hz, use a 2 MHz clock. The source of the master clock is selected by setting the CLOCKSEL bits (Bits[3:2]) in the ADC mode register as shown in Table 19. The default operation on power-up and reset of the AD7172-2 is to operate with the internal oscillator. It is possible to fine tune the output data rate and filter notch at low output data rates using the SINC3_MAPx bit (Bit 7 of the FILTCONx registers). See the Sinc3 Filter section for more information.

Internal Oscillator

The internal oscillator runs at 16 MHz, is internally divided down to 2 MHz for the modulator, and can be used as the ADC master clock. The internal oscillator is the default clock source for the AD7172-2 and is specified with an accuracy of ±2.5%.

There is an option to allow the internal clock oscillator to be output on the XTAL2/CLKIO pin. The clock output is driven to the IOVDD logic level. Use of this option can affect the dc performance of the AD7172-2 due to the disturbance introduced by the output driver. The extent to which the performance is affected depends on the IOVDD voltage supply. Higher IOVDD voltages create a wider logic output swing from the driver and affect performance to a greater extent. This effect is further exaggerated if the IOSTRENGTH bit is set at higher IOVDD levels (see Table 29 for more information).

External Crystal

If higher precision, lower jitter clock sources are required, the AD7172-2 can use an external crystal to generate the master clock. The crystal is connected to the XTAL1 and XTAL2/CLKIO pins. A recommended crystal for use is the FA-20H, a 16 MHz, 10 ppm, 9 pF crystal from Epson-Toyocom that is available in a surface-mount package. As shown in Figure 56, insert two capacitors from the traces connecting the crystal to the XTAL1 and XTAL2/CLKIO pins. These capacitors allow circuit tuning. Connect these capacitors to the DGND pin. The value for these capacitors depends on the length and capacitance of the trace connections between the crystal and the XTAL1 and XTAL2/CLKIO pins. Therefore, the values of these capacitors differ depending on the printed circuit board (PCB) layout and the crystal employed.

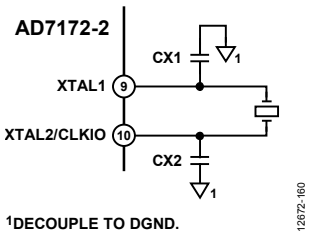

Figure 56. External Crystal Connections

The external crystal circuitry can be sensitive to the SCLK edges, depending on SCLK frequency, IOVDD voltage, crystal circuitry layout, and the crystal used. During crystal startup, any disturbances caused by the SLCK edges can cause double edges on the crystal input, resulting in invalid conversions until the crystal voltage has reached a high enough level such that any interference from the SCLK edges is insufficient to cause double clocking. This double clocking can be avoided by ensuring that the crystal circuitry has reached a sufficient voltage level after startup before applying any SCLK.

Due to the nature of the crystal circuitry, it is recommended that empirical testing of the circuit be performed under the required conditions, with the final PCB layout and crystal, to ensure correct operation.

External Clock

The AD7172-2 can also use an externally supplied clock. In systems where this is desirable, the external clock is routed to the XTAL2/CLKIO pin. In this configuration, the XTAL2/CLKIO pin accepts the externally sourced clock and routes it to the modulator. The logic level of this clock input is defined by the voltage applied to the IOVDD pin.

DIGITAL FILTERS

The AD7172-2 has three flexible filter options to allow optimization of noise, settling time, and rejection:

- Sinc5 + sinc1 filter
- Sinc3 filter
- Enhanced 50 Hz and 60 Hz rejection filters

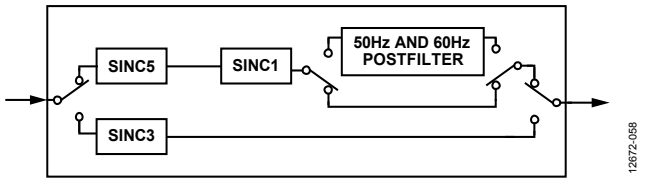

Figure 57. Digital Filter Block Diagram

The filter and output data rate are configured by setting the appropriate bits in the filter configuration register for the selected setup. Each channel can use a different setup and, therefore, a different filter and output data rate. See the Register Details section for more information.

SINC5 + SINC1 FILTER

The sinc5 + sinc1 filter is targeted at multiplexed applications and achieves single cycle settling at output data rates of 2.6 kSPS and less. The sinc5 block output is fixed at the maximum rate of 31.25 kSPS, and the sinc1 block output data rate can be varied to control the final ADC output data rate. Figure 58 shows the frequency domain response of the sinc5 + sinc1 filter at a 50 SPS output data rate. The sinc5 + sinc1 filter has a slow roll-off over frequency and narrow notches.

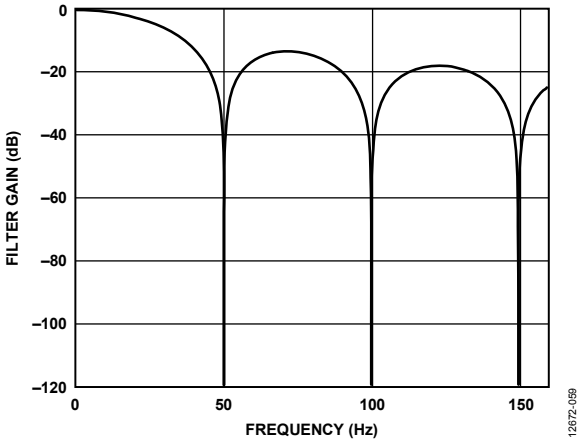

Figure 58. Sinc5 + Sinc1 Filter Response at 50 SPS ODR

The output data rates with the accompanying settling time and rms noise for the sinc5 + sinc1 filter are shown in Table 20 and Table 21.

SINC3 FILTER

The sinc3 filter achieves the best single-channel noise performance at lower rates and is, therefore, most suitable for single-channel applications. The sinc3 filter always has a settling time equal to

$$t_{SETTLE} = 3/Output\ Data\ Rate$$

Figure 59 shows the frequency domain filter response for the sinc3 filter. The sinc3 filter has good roll-off over frequency and has wide notches for good notch frequency rejection.

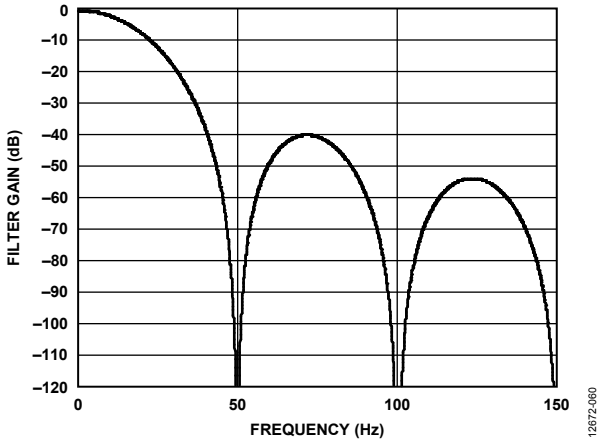

Figure 59. Sinc3 Filter Response

The output data rates with the accompanying settling time and rms noise for the sinc3 filter are shown in Table 22 and Table 23. It is possible to fine tune the output data rate for the sinc3 filter by setting the SINC3_MAPx bit in the filter configuration registers. If this bit is set, the mapping of the filter register changes to directly program the decimation rate of the sinc3 filter. All other options are eliminated. The data rate when on a single channel can be calculated using the following equation:

$$Output\ Data\ Rate = \frac{f_{MOD}}{32 \times FILTCONx[14:0]}$$

where:
f_{MOD} is the modulator rate (MCLK/2) and is equal to 1 MHz.
FILTCONx[14:0] are the contents on the filter configuration registers excluding the MSB.

For example, an output data rate of 50 SPS can be achieved with SINC3_MAPx enabled by setting the FILTCONx[14:0] bits to a value of 625.

SINGLE CYCLE SETTLING

The AD7172-2 can be configured by setting the SING_CYC bit in the ADC mode register so that only fully settled data is output, thus effectively putting the ADC into a single cycle settling mode. This mode achieves single cycle settling by reducing the output data rate to be equal to the settling time of the ADC for the selected output data rate. This bit has no effect with the sinc5 + sinc1 filter at output data rates of 2.6 kSPS and less.

Figure 60 shows a step on the analog input with single cycle settling mode disabled and the sinc3 filter selected. The analog input requires at least three cycles after the step change for the output to reach the final settled value.

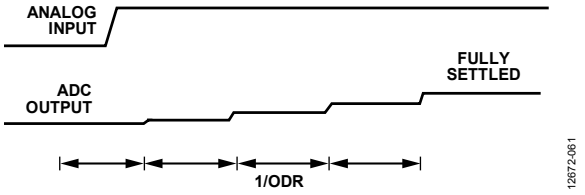

Figure 60. Step Input Without Single Cycle Settling

Figure 61 shows the same step on the analog input but with single cycle settling enabled. The analog input requires at least a single cycle for the output to be fully settled. The output data rate, as indicated by the $\overline{RDY}$ signal, is now reduced to equal the settling time of the filter at the selected output data rate.

ENHANCED 50 Hz AND 60 Hz REJECTION FILTERS

The enhanced filters provide rejection of 50 Hz and 60 Hz simultaneously and allow the user to trade off settling time and rejection. These filters can operate up to 27.27 SPS or can reject up to 90 dB of 50 Hz ± 1 Hz and 60 Hz ± 1 Hz interference.

These filters are realized operated by postfiltering the output of the sinc5 + sinc1 filter. For this reason, the sinc5 + sinc1 filter must be selected when using the enhanced filters to achieve the specified settling time and noise performance. Table 24 shows the output data rates with the accompanying settling time, rejection, and rms noise. Figure 62 to Figure 69 show the frequency domain plots of the responses from the enhanced filters.

Table 24. Enhanced Filters Output Data Rate, Noise, Settling Time, and Rejection Using the Enhanced Filters

Output Data Rate (SPS)	Settling Time (ms)	Simultaneous Rejection of 50 Hz ± 1 Hz and 60 Hz ± 1 Hz (dB)[1]	Noise (μV rms)	Peak-to-Peak Resolution (Bits)	Comments
27.27	36.67	47	0.45	21.4	See Figure 62 and Figure 65

OPERATING MODES

The AD7172-2 has a number of operating modes that can be set from the ADC mode register and interface mode register (see Table 28 and Table 29). These modes are as follows and are described in the following sections:

- Continuous conversion mode
- Continuous read mode
- Single conversion mode
- Standby mode
- Power-down mode
- Calibration modes (three)

CONTINUOUS CONVERSION MODE

Continuous conversion is the default power-up mode. The AD7172-2 converts continuously, and the $\overline{RDY}$ bit in the status register goes low each time a conversion is complete. If $\overline{CS}$ is low, the $\overline{RDY}$ output also goes low when a conversion is complete. To read a conversion, the user writes to the communications register, indicating that the next operation is a read of the data register. When the data-word has been read from the data register, the DOUT/$\overline{RDY}$ pin goes high.

The user can read this register additional times, if required. However, the user must ensure that the data register is not being accessed at the completion of the next conversion; otherwise, the new conversion word is lost.

When several channels are enabled, the ADC automatically sequences through the enabled channels, performing one conversion on each channel. When all the channels have been converted, the sequence starts again with the first channel. The channels are converted in order from the lowest enabled channel to the highest enabled channel. The data register is updated as soon as each conversion is available. The $\overline{RDY}$ output pulses low each time a conversion is available. The user can then read the conversion while the ADC converts the next enabled channel.

If the DATA_STAT bit in the interface mode register is set to 1, the contents of the status register, along with the conversion data, are output each time the data register is read. The status register indicates the channel to which the conversion corresponds.

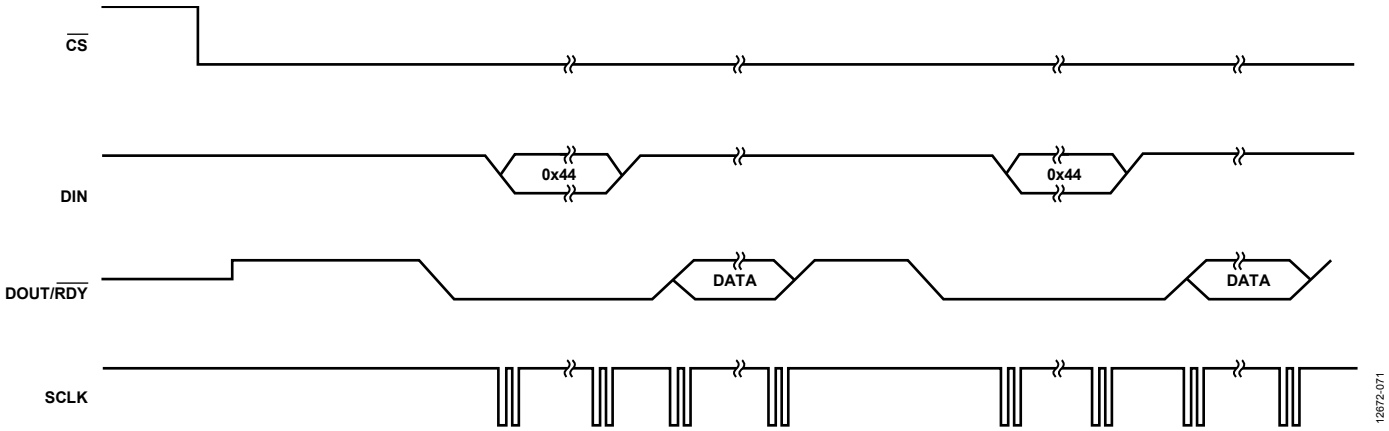

Figure 70. Continuous Conversion Mode

CONTINUOUS READ MODE

In continuous read mode, it is not required to write to the communications register before reading ADC data; apply only the required number of SCLKs after the $\overline{RDY}$ output goes low to indicate the end of a conversion. When the conversion is read, the $\overline{RDY}$ output returns high until the next conversion is available. In this mode, the data can be read only once. The user must also ensure that the data-word is read before the next conversion is complete. If the user has not read the conversion before the completion of the next conversion or if insufficient serial clocks are applied to the AD7172-2 to read the data-word, the serial output register is reset shortly before the next conversion is complete, and the new conversion is placed in the output serial register. The ADC must be configured for continuous conversion mode to use continuous read mode.

To enable continuous read mode, set the CONTREAD bit in the interface mode register. When this bit is set, the only serial interface operations possible are reads from the data register. To exit continuous read mode, issue a dummy read of the ADC data register command (0x44) while the $\overline{RDY}$ output is low. Alternatively, apply a software reset, that is, 64 SCLKs with $\overline{CS}$ = 0 and DIN = 1. This resets the ADC and all register contents. These are the only commands that the interface recognizes after it is placed in continuous read mode. Hold DIN low in continuous read mode until an instruction is to be written to the device.

If multiple ADC channels are enabled, each channel is output in turn, with the status bits being appended to the data if the DATA_STAT bit is set in the interface mode register. The status register indicates the channel to which the conversion corresponds.

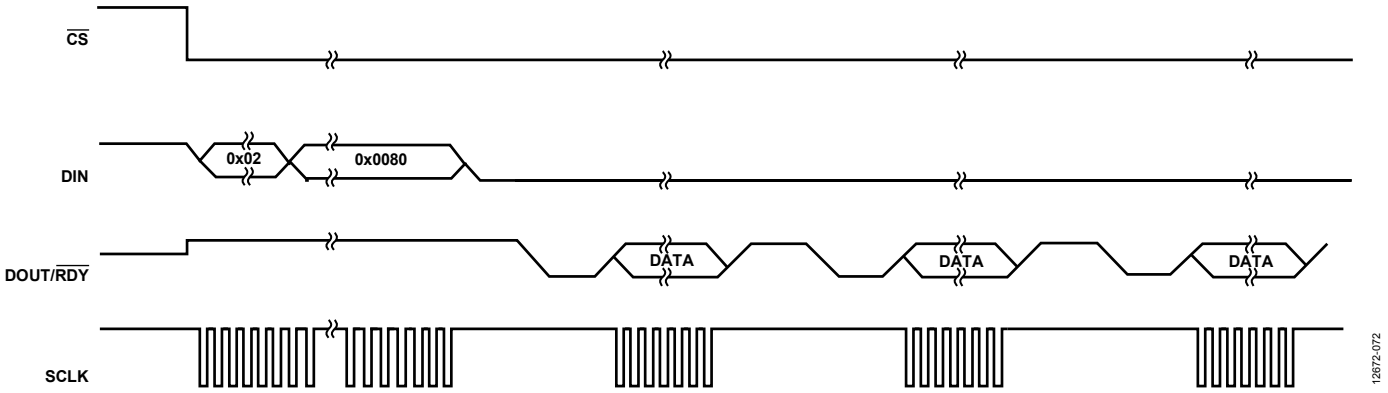

Figure 71. Continuous Read Mode

SINGLE CONVERSION MODE

In single conversion mode, the AD7172-2 performs a single conversion and is placed in standby mode after the conversion is complete. The $\overline{RDY}$ output goes low to indicate the completion of a conversion. When the data-word has been read from the data register, the $\overline{RDY}$ output goes high. The data register can be read several times, if required, even when the $\overline{RDY}$ output has gone high.

If several channels are enabled, the ADC automatically sequences through the enabled channels and performs a conversion on each channel. When a conversion is started, the $\overline{RDY}$ output goes high and remains high until a valid conversion is available and $\overline{CS}$ is low.

When the conversion is available, the $\overline{RDY}$ output goes low. The ADC then selects the next channel and begins a conversion. The user can read the present conversion while the next conversion is being performed. When the next conversion is complete, the data register is updated; therefore, the user has a limited period in which to read the conversion. When the ADC has performed a single conversion on each of the selected channels, it returns to standby mode.

If the DATA_STAT bit in the interface mode register is set to 1, the contents of the status register, along with the conversion, are output each time the data register is read. The two LSBs of the status register indicate the channel to which the conversion corresponds.

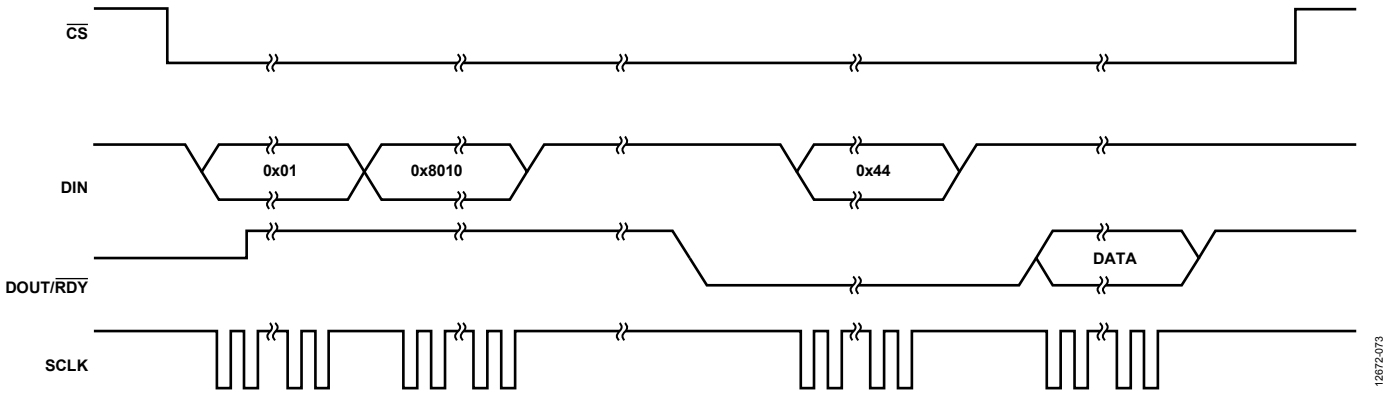

Figure 72. Single Conversion Mode

STANDBY AND POWER-DOWN MODES

In standby mode, most blocks are powered down. The LDO regulators remain active so that the registers maintain their contents. The internal reference remains active if enabled, and the crystal oscillator remains active if selected. To power down the reference in standby mode, set the REF_EN bit in the ADC mode register to 0. To power down the clock in standby mode, set the CLOCKSEL bits in the ADC mode register to 00 (internal oscillator).

In power-down mode, all blocks are powered down, including the LDO regulators. All registers lose their contents, and the GPIO outputs are placed in three-state. To prevent accidental entry to power-down mode, the ADC must first be placed in standby mode. Exiting power-down mode requires 64 SCLKs with $\overline{CS}$ = 0 and DIN = 1, that is, a serial interface reset. A delay of 500 µs is recommended before issuing a subsequent serial interface command to allow the LDO regulator to power up.

CALIBRATION

The AD7172-2 allows a two-point calibration to be performed to eliminate any offset and gain errors. Three calibration modes eliminate these offset and gain errors on a per setup basis:

- Internal zero-scale calibration mode
- System zero-scale calibration mode
- System full-scale calibration mode

There is no internal full-scale calibration mode because this is calibrated in the factory at the time of production.

Only one channel can be active during calibration. After each conversion, the ADC conversion result is scaled using the ADC calibration registers before being written to the data register.

The default value of the offset register is 0x800000, and the nominal value of the gain register is 0x555555. The calibration range of the ADC gain is from 0.4 × V_{REF} to 1.05 × V_{REF}. The following equations show the calculations that are used. In unipolar mode, the ideal relationship—that is, not taking into account the ADC gain error and offset error—is as follows:

$$Data = \left[\frac{0.75 \times V_{IN}}{V_{REF}} \times 2^{23} - (Offset - 0\,x\,800000)\right] \times \frac{Gain}{0\,x\,400000} \times 2$$

In bipolar mode, the ideal relationship—that is, not taking into account the ADC gain error and offset error—is as follows:

$$Data = \left[\frac{0.75 \times V_{IN}}{V_{REF}} \times 2^{23} - (Offset - 0\,x\,800000)\right] \times \frac{Gain}{0\,x\,400000} + 0\,x\,800000$$

To start a calibration, write the relevant value to the mode bits (Bits[6:4]) in the ADC mode register. The DOUT/$\overline{RDY}$ pin and the $\overline{RDY}$ bit (Bit 7) in the status register go high when the calibration initiates. When the calibration is complete, the contents of the corresponding offset or gain register are updated, the $\overline{RDY}$ bit in the status register is reset, the $\overline{RDY}$ output pin returns low (if $\overline{CS}$ is low), and the AD7172-2 reverts to standby mode.

During an internal offset calibration, the selected positive analog input pin is disconnected, and both modulator inputs are connected internally to the selected negative analog input pin. Therefore, it is necessary to ensure that the voltage on the selected negative analog input pin does not exceed the allowed limits and is free from excessive noise and interference.

However, for system calibrations, the system zero-scale (offset) and system full-scale (gain) voltages must be applied to the ADC pins before initiating the calibration modes. As a result, errors external to the ADC are removed.

From an operational point of view, treat a calibration like another ADC conversion. An offset calibration, if required, must always be performed before a full-scale calibration. Set the system software to monitor the $\overline{RDY}$ bit in the status register or the $\overline{RDY}$ output to determine the end of a calibration via a polling sequence or an interrupt-driven routine. All calibrations require a time equal to the settling time of the selected filter and output data rate to be completed.

An internal offset calibration, system zero-scale calibration, and system full-scale calibration can be performed at any output data rate. Using lower output data rates results in better calibration accuracy and is accurate for all output data rates. A new offset calibration is required for a given channel if the reference source for that channel is changed.

The offset error is typically ±40 µV, and an offset calibration reduces the offset error to the order of the noise. The gain error is factory calibrated at ambient temperature. Following this calibration, the gain error is typically ±35 ppm of FSR.

The AD7172-2 provides the user with access to the on-chip calibration registers, allowing the microprocessor to read the calibration coefficients of the device and to write calibration coefficients. A read or write of the offset and gain registers can be performed at any time except during an internal or self calibration.

DIGITAL INTERFACE

The programmable functions of the AD7172-2 are controlled via the SPI. The serial interface of the AD7172-2 consists of four signals: $\overline{CS}$, DIN, SCLK, and DOUT/$\overline{RDY}$. The DIN input transfers data into the on-chip registers, and the DOUT output accesses data from the on-chip registers. SCLK is the serial clock input for the device, and all data transfers (either on DIN input or on DOUT output) occur with respect to the SCLK signal.

The DOUT/$\overline{RDY}$ pin also functions as a data ready signal, with the output going low if $\overline{CS}$ is low when a new data-word is available in the data register. The $\overline{RDY}$ output is reset high when a read operation from the data register is complete. The $\overline{RDY}$ output also goes high before updating the data register to indicate when not to read from the device to ensure that a data read is not attempted while the register is being updated. Take care to avoid reading from the data register when the $\overline{RDY}$ output is about to go low. The best method to ensure that no data read occurs is to always monitor the $\overline{RDY}$ output; start reading the data register as soon as the $\overline{RDY}$ output goes low; and ensure a sufficient SCLK rate, such that the read is completed before the next conversion result. $\overline{CS}$ selects a device. $\overline{CS}$ can decode the AD7172-2 in systems where several components are connected to the serial bus.

Figure 2 and Figure 3 show timing diagrams for interfacing to the AD7172-2 using $\overline{CS}$ to decode the device. Figure 2 shows the timing for a read operation from the AD7172-2, and Figure 3 shows the timing for a write operation to the AD7172-2. It is possible to read from the data register several times even though the $\overline{RDY}$ output returns high after the first read operation. However, ensure that the read operations are completed before the next output update occurs. In continuous read mode, the data register can be read only once.

The serial interface can operate in 3-wire mode by tying $\overline{CS}$ low. In this case, the SCLK, DIN, and DOUT/$\overline{RDY}$ pins communicate with the AD7172-2. The end of the conversion can also be monitored using the $\overline{RDY}$ bit in the status register.

The AD7172-2 can be reset by writing 64 SCLKs with $\overline{CS}$ = 0 and DIN = 1. A reset returns the interface to the state in which it expects a write to the communications register. This operation resets the contents of all registers to their power-on values. Following a reset, allow a period of 500 µs before addressing the serial interface.

CHECKSUM PROTECTION

The AD7172-2 has a checksum mode that can improve interface robustness. Using the checksum ensures that only valid data is written to a register and allows data read from a register to be validated. If an error occurs during a register write, the CRC_ERROR bit is set in the status register. However, to ensure that the register write was successful, read back the register and verify the checksum.

For CRC checksum calculations during a write operation, the following polynomial is always used:

$$x^8 + x^2 + x + 1$$

During read operations, the user can select between this polynomial and a simpler exclusive or (XOR) function. The XOR function requires less time to process on the host microcontroller than the polynomial-based checksum. The CRC_EN bits in the interface mode register enable and disable the checksum and allow the user to select between the polynomial check and the simple XOR check.

The checksum is appended to the end of each read and write transaction. The checksum calculation for the write transaction is calculated using the 8-bit command word and the 8-bit to 24-bit data. For a read transaction, the checksum is calculated using the command word and the 8-bit to 32-bit data output. Figure 73 and Figure 74 show SPI write and read transactions, respectively.

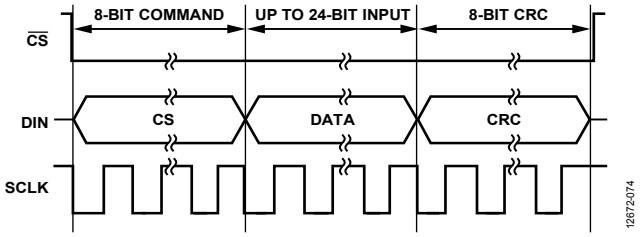

Figure 73. SPI Write Transaction with CRC

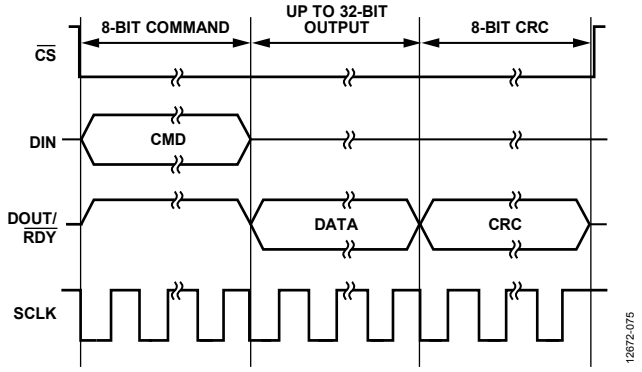

Figure 74. SPI Read Transaction with CRC

If checksum protection is enabled when continuous read mode is active, an implied read data command of 0x44 before every data transmission must be accounted for when calculating the checksum value. This implied read data command ensures a nonzero checksum value even if the ADC data equals 0x000000.

CRC CALCULATION

Polynomial

The checksum, which is eight bits wide, is generated using the polynomial

$$x^8 + x^2 + x + 1$$

To generate the checksum, the data is left shifted by eight bits to create a number ending in eight Logic 0s.

The polynomial is aligned so that the MSB is adjacent to the leftmost Logic 1 of the data. An XOR function is applied to the data to produce a new, shorter number. The polynomial is again aligned so that the MSB is adjacent to the leftmost Logic 1 of the new result, and the procedure is repeated. This process repeats until the original data is reduced to a value less than the polynomial. This is the 8-bit checksum.

Example of a Polynomial CRC Calculation—24-Bit Word: 0x654321 (8-Bit Command and 16-Bit Data)

An example of generating the 8-bit checksum using the polynomial based checksum is as follows:

```
Initial value          011001010100001100100001
                       011001010100001100100001 00000000      left shifted eight bits
x^8 + x^2 + x + 1  =       100000111                          polynomial
  100100100000110010000100000000                  XOR result
  100000111                                       polynomial
    100011000110010000100000000                   XOR result
    100000111                                     polynomial
      111111100100001000000000                    XOR result
      100000111                                   polynomial value
       111110111000010000000                      XOR result
       100000111                                  polynomial value
        111100000000100000000                     XOR result
        100000111                                 polynomial value
         11100111000100000000                     XOR result
         100000111                                polynomial value
          1100100100100000000                     XOR result
          100000111                               polynomial value
           100101010100000000                     XOR result
           100000111                              polynomial value
              101101100000000                     XOR result
              100000111                           polynomial value
                1101011000000                     XOR result
                100000111                         polynomial value
                 101010110000                     XOR result
                 100000111                        polynomial value
                   1010001000                     XOR result
                   100000111                      polynomial value
                     10000110                     checksum = 0x86
```

XOR Calculation

The checksum, which is 8 bits wide, is generated by splitting the data into bytes and then performing an XOR of the bytes.

Example of an XOR Calculation—24-Bit Word: 0x654321 (8-Bit Command and 16-Bit Data)

Using the previous example, divide into three bytes: 0x65, 0x43, and 0x21

01100101	0x65
01000011	0x43
00100110	XOR result
00100001	0x21
00000111	CRC

INTEGRATED FUNCTIONS

The AD7172-2 has integrated functions that improve the usefulness of a number of applications as well as serve diagnostic purposes in safety conscious applications.

GENERAL-PURPOSE INPUT/OUTPUT

The AD7172-2 has two general-purpose digital input/output pins: GPIO0 and GPIO1. They are enabled using the IP_EN0/IP_EN1 bits or the OP_EN0/OP_EN1 bits in the GPIOCON register. When the GPIO0 or GPIO1 pin is enabled as an input, the logic level at the pin is contained in the GP_DATA0 or GP_DATA1 bit, respectively. When the GPIO0 or GPIO1 pin is enabled as an output, the GP_ DATA0 or GP_DATA1 bits, respectively, determine the logic level output at the pin. The logic levels for these pins are referenced to AVDD1 and AVSS; therefore, outputs have an amplitude of 5 V or 3.3 V.

The $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ pin can also be used as a general-purpose output. When the ERR_EN bits in the GPIOCON register are set to 11, the $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$A pin operates as a general-purpose output. In this configuration, the ERR_DAT bit in the GPIOCON register determines the logic level output at the pin. The logic level for the pin is referenced to IOVDD and DGND.

The GPIO0 pin, GPIO1 pin, and $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ pin, when set as general-purpose outputs, have an active pull-up.

EXTERNAL MULTIPLEXER CONTROL

If an external multiplexer increases the channel count, the multiplexer logic pins can be controlled via the AD7172-2 GPIOx pins. With the MUX_IO bit (Bit 12 in the GPIOCON register), the GPIOx timing is controlled by the ADC; therefore, the channel change is synchronized with the ADC, eliminating any need for external synchronization.

DELAY

It is possible to insert a programmable delay before the AD7172-2 begins to take samples. This delay allows an external amplifier or multiplexer to settle and can also alleviate the specification requirements for the external amplifier or multiplexer. Eight programmable settings, ranging from 0 µs to 8 ms, can be set using the delay bits in the ADC mode register (Register 0x01, Bits[10:8]).

If a delay greater than 0 µs is selected and the HIDE_DELAY bit in the ADC mode register is set to 0, this delay is added to the conversion time, regardless of selected output data rate.

When using the sinc5 + sinc1 filter, it is possible to hide this delay so the output data rate remains the same as the output data rate without the delay enabled. If the HIDE_DELAY bit is set to 1 and the selected delay is less than half of the conversion time, the delay can be absorbed by reducing the number of averages the digital filter performs, which keeps the conversion time the same but can affect the noise performance.

The effect on the noise performance depends on the delay time compared to the conversion time. It is possible to absorb the delay only for output data rates less than 2.6 kSPS with the exception of the following four rates, which cannot absorb any delay: 381 SPS, 59.52 SPS, 49.68 SPS, and 16.66 SPS.

16-BIT/24-BIT CONVERSIONS

By default, the AD7172-2 generates 24-bit conversions. However, the width of the conversions can be reduced to 16 bits. Setting the WL16 bit in the interface mode register to 1 rounds all data conversions to 16 bits. Clearing this bit sets the width of the data conversions to 24 bits.

DOUT_RESET

The serial interface uses a shared DOUT/$\overline{\text{RDY}}$ pin. By default, this pin outputs the $\overline{\text{RDY}}$ signal. During a data read, this pin outputs the data from the register being read. After the read is complete, the pin reverts to outputting the $\overline{\text{RDY}}$ signal after a short fixed period of time (t_7). However, this time may be too short for some microcontrollers and can be extended until the $\overline{\text{CS}}$ pin is brought high by setting the DOUT_RESET bit in the interface mode register to 1. This setting means $\overline{\text{CS}}$ must frame each read operation and compete the serial interface transaction.

SYNCHRONIZATION

Normal Synchronization

When the SYNC_EN bit in the GPIOCON register is set to 1, the $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ pin functions as a synchronization input. The $\overline{\text{SYNC}}$ input allows the user to reset the modulator and the digital filter without affecting any of the setup conditions on the device. This feature allows the user to start to gather samples of the analog input from a known point, the rising edge of the $\overline{\text{SYNC}}$ input. The $\overline{\text{SYNC}}$ input must be low for at least one master clock cycle to ensure that synchronization occurs.

If multiple AD7172-2 devices are operated from a common master clock, they can be synchronized so the analog inputs aresampled simultaneously. This synchronization is typically completed after each AD7172-2 device has performed each respective calibration or has calibration coefficients loaded into the calibration registers. A falling edge on the $\overline{\text{SYNC}}$ input resets the digital filter and the analog modulator and places the AD7172-2 into a consistent known state. While the $\overline{\text{SYNC}}$ input is low, the AD7172-2 is maintained in this known state. On the $\overline{\text{SYNC}}$ input rising edge, the modulator and filter are taken out of this reset state, and on the next master clock edge, the device starts to gather input samples again.

The device is taken out of reset on the master clock falling edge following the SYNC input low to high transition. Therefore, when multiple devices are being synchronized, take the SYNC Ainput high on the master clock rising edge to ensure that all devices are released on the master clock falling edge. If the SYNC input is not taken high in sufficient time, a difference of one master clock cycle between the devices is possible, that is, the instant at which conversions are available differs from device to device by a maximum of one master clock cycle.

The SYNC input can also be used as a start conversion command for a single channel when in normal synchronization mode. In this mode, the rising edge of SYNC input starts a conversion, and the falling edge of the RDY output indicates when the conversion is complete. The settling time of the filter is required for each data register update. After the conversion is complete, bring the SYNC input low in preparation for the next conversion start signal.

Alternate Synchronization

In alternate synchronization mode, the SYNC input operates as a start conversion command when several channels of the AD7172-2 are enabled. Setting the ALT_SYNC bit in the interface mode register to 1 enables an alternate synchronization scheme. When the SYNC input is taken low, the ADC completes the conversion on the current channel, selects the next channel in the sequence, and then waits until the SYNC input is taken high to start the conversion. The RDY output goes low when the conversion is complete on the current channel, and the data register is updated with the corresponding conversion. Therefore, the SYNC input does not interfere with the sampling on the currently selected channel but allows the user to control the instant at which the conversion begins on the next channel in the sequence.

Alternate synchronization mode can be used only when several channels are enabled. It is not recommended to use this mode when a single channel is enabled.

ERROR FLAGS

The status register contains three error bits (ADC_ERROR, CRC_ERROR, and REG_ERROR) that flag errors with the ADC conversion, errors with the CRC check, and errors caused by changes in the registers, respectively. In addition, the ERROR output can indicate that an error has occurred.

ADC_ERROR

The ADC_ERROR bit in the status register flags any errors that occur during the conversion process. The flag is set when an over-range or underrange result is output from the ADC. The ADC also outputs all 0s or all 1s when an undervoltage or overvoltage occurs. This flag is reset only when the overvoltage or undervoltage condition is removed. This flag is not reset by a read of the data register.

CRC_ERROR

If the CRC value that accompanies a write operation does not correspond with the information sent, the CRC_ERROR flag is set. The flag is reset when the status register is explicitly read.

REG_ERROR

The REG_ERROR flag is used in conjunction with the REG_CHECK bit in the interface mode register. When the REG_CHECK bit is set, the AD7172-2 monitors the values in the on-chip registers. If a bit changes, the REG_ERROR bit is set to 1. Therefore, for writes to the on-chip registers, set the REG_CHECK bit to 0. When the registers have been updated, the REG_CHECK bit can be set to 1. The AD7172-2 calculates a checksum of the on-chip registers. If one of the register values has changed, the REG_ERROR bit is set to 1. If an error is flagged, the REG_CHECK bit must be set to 0 to clear the REG_ERROR bit in the status register. The register check function does not monitor the data register, status register, or interface mode register.

ERROR Input/Output

When the SYNC_EN bit in the GPIOCON register is set to 0, the SYNC/ERROR pin functions as an error input/output pin or a general-purpose output pin. The ERR_EN bits in the GPIOCON register determine the function of the pin.

When the ERR_EN bits are set to 10, the SYNC/ERROR pin functions as an open-drain error output, ERROR. The three error bits in the status register (ADC_ERROR, CRC_ERROR, and REG_ERROR) are OR'ed, inverted, and mapped to the ERROR output. Therefore, the ERROR output indicates that an error has occurred. The status register must be read to identify the error source.

When the ERR_EN bits are set to 01, the SYNC/ERROR pin functions as an error input, ERROR. The error output of another component can be connected to the AD7172-2 ERROR input so that the AD7172-2 indicates when an error occurs on either itself or the external component. The value on the ERROR input is inverted and OR'ed with the errors from the ADC conversion, and the result is indicated via the ADC_ERROR bit in the status register. The value of the ERROR input is reflected in the ERR_DAT bit in the GPIO configuration register.

The ERROR input/output is disabled when the ERR_EN bits are set to 00. When the ERR_EN bits are set to 11, the SYNC/ERROR pin operates as a general-purpose output.

DATA_STAT

The contents of the status register can be appended to each conversion on the AD7172-2 using the DATA_STAT bit in the IFMODE register. This function is useful if several channels are enabled. Each time a conversion is output, the contents of the status register are appended. The two LSBs of the status register indicate to which channel the conversion corresponds. In addition, the user can determine if any errors are being flagged by the error bits.

IOSTRENGTH

The serial interface can operate with a power supply as low as 2 V. However, at this low voltage, the DOUT/RDY pin may not have sufficient drive strength if there is moderate parasitic capacitance on the board or if the SCLK frequency is high. The IOSTRENGTH bit in the interface mode register increases the drive strength of the DOUT/RDY pin.

INTERNAL TEMPERATURE SENSOR

The AD7172-2 has an integrated temperature sensor. The temperature sensor can be used as a guide for the ambient temperature at which the device is operating. This can be used for diagnostic purposes or as an indicator of when the application circuit must rerun a calibration routine to take into account a shift in operating temperature. The temperature sensor is selected using the crosspoint multiplexer and is selected in the same way as an analog input channel.

The temperature sensor requires that the analog input buffers be enabled on both analog inputs. If the buffers are not enabled, selecting the temperature sensor as an input forces the buffers to be enabled during the conversion.

To use the temperature sensor, the first step is to calibrate the device in a known temperature (25°C) and take a conversion as a reference point. The temperature sensor has a nominal sensitivity of 477 µV/K; the difference in this ideal slope and the slope measured can calibrate the temperature sensor. The temperature sensor is specified with a ±2°C typical accuracy after calibration at 25°C. The temperature can be calculated as follows:

$$Temperature\,(°C) = \left(\frac{Conversion\ Result}{477\ \mu V} \right) - 273.15$$

GROUNDING AND LAYOUT

The analog inputs and reference inputs are differential and, therefore, most of the voltages in the analog modulator are common-mode voltages. The high common-mode rejection of the device removes common-mode noise on these inputs. The analog and digital supplies to the AD7172-2 are independent and connected to separate pins to minimize coupling between the analog and digital sections of the device. The digital filter provides rejection of broadband noise on the power supplies, except at integer multiples of the master clock frequency.

The digital filter also removes noise from the analog and reference inputs, provided that these noise sources do not saturate the analog modulator. As a result, the AD7172-2 is more immune to noise interference than a conventional high resolution converter. However, because the resolution of the AD7172-2 is high and the noise levels from the converter are so low, take care with regard to grounding and layout.

The PCB that houses the ADC must be designed such that the analog and digital sections are separated and confined to certain areas of the board. A minimum etch technique is generally best for ground planes because it results in the best shielding.

In any layout, the user must consider the flow of currents in the system, ensuring that the paths for all return currents are as close as possible to the paths the currents took to reach their destinations.

Avoid running digital lines under the device because this couples noise onto the die. Allow the analog ground plane to run under the AD7172-2 to prevent noise coupling. The power supply lines to the AD7172-2 must use as wide a trace as possible to provide low impedance paths and reduce glitches on the power supply line. Shield fast switching signals like clocks with digital ground to prevent radiating noise to other sections of the board, and never run clock signals near the analog inputs. Avoid crossover of digital and analog signals. Run traces on opposite sides of the board at right angles to each other. This technique reduces the effects of feedthrough on the board. A microstrip technique is by far the best but is not always possible with a double-sided board.

Good decoupling is important when using high resolution ADCs. The AD7172-2 has three power supply pins: AVDD1, AVDD2, and IOVDD. The AVDD1 and AVDD2 pins are referenced to AVSS, and the IOVDD pin is referenced to DGND. Decouple AVDD1 and AVDD2 with a 10 µF capacitor in parallel with a 0.1 µF capacitor to AVSS on each pin. Place the 0.1 µF capacitor as close as possible to the device on each supply, ideally right up against the device. Decouple IOVDD with a 10 µF capacitor in parallel with a 0.1 µF capacitor to DGND. Decouple all analog inputs to AVSS. If an external reference is used, decouple the REF+ and REF− pins to AVSS.

The AD7172-2 also has two on-board LDO regulators, one that regulates the AVDD2 supply and one that regulates the IOVDD supply. For the REGCAPA pin, use 1 µF and 0.1 µF capacitors to AVSS. Similarly, for the REGCAPD pin, use 1 µF and 0.1 µF capacitors to DGND.

If using the AD7172-2 for split supply operation, a separate plane must be used for AVSS.

REGISTER SUMMARY

REGISTER DETAILS

COMMUNICATIONS REGISTER

Address: 0x00, Reset: 0x00, Name: COMMS

All access to the on-chip registers must start with a write to the communications register. This write determines what register is accessed next and whether that operation is a write or a read.

Table 26. Bit Descriptions for COMMS

Bits	Bit Name	Settings	Description	Reset	Access
7	$\overline{WEN}$		This bit must be low to begin communications with the ADC.	0x0	W
6	R/$\overline{W}$		This bit determines if the command is a read or write operation.	0x0	W
		0	Write command		
		1	Read command

		111011	Gain Register 3		

STATUS REGISTER

Address: 0x00, Reset: 0x80, Name: STATUS

The status register is an 8-bit register that contains ADC and serial interface status information. It can optionally be appended to the data register by setting the DATA_STAT bit in the interface mode register.

Table 27. Bit Descriptions for STATUS

Bits	Bit Name	Settings	Description	Reset	Access
7	$\overline{\text{RDY}}$		The status of $\overline{\text{RDY}}$ is output to the DOUT/$\overline{\text{RDY}}$ pin whenever $\overline{\text{CS}}$ is low and a register is not being read. This bit goes low when the ADC has written a new result to the data register. In ADC calibration modes, this bit goes low when the ADC has written the calibration result. $\overline{\text{RDY}}$ is brought high automatically by a read of the data register.	0x1	R
		0	New data result available		
		1	Awaiting new data result		
6	ADC_ERROR		This bit by default indicates if an ADC overrange or underrange has occurred. The ADC result is clamped to 0xFFFFFF for overrange errors and 0x000000 for underrange errors. This bit is updated when the ADC result is written and is cleared at the next update after removing the overrange or underrange condition.	0x0	R
		0	No error		
		1	Error		
5	CRC_ERROR		This bit indicates if a CRC error has taken place during a register write. For register reads, the host microcontroller determines if a CRC error has occurred. This bit is cleared by a read of this register.	0x0	R
		0	No error		
		1	CRC error		
4	REG_ERROR		This bit indicates if the content of one of the internal registers has changed from the value calculated when the register integrity check was activated. The check is activated by setting the REG_CHECK bit in the interface mode register. This bit is cleared by clearing the REG_CHECK bit.	0x0	R
		0	No error		
		1	Error		
[3:2]	RESERVED		These bits are reserved.	0x0	R
[1:0]	CHANNEL		These bits indicate which channel was active for the ADC conversion whose result is currently in the data register. This channel may be different from the channel currently being converted. The mapping is a direct map from the channel register; therefore, Channel 0 results in 0x0 and Channel 3 results in 0x3.	0x0	R
		00	Channel 0		
		01	Channel 1		
		10	Channel 2		
		11	Channel 3		

ADC MODE REGISTER

Address: 0x01, Reset: 0x0000, Name: ADCMODE

The ADC mode register controls the operating mode of the ADC and the master clock selection. A write to the ADC mode register resets the filter and the $\overline{\text{A}}$RDY$\overline{\text{A}}$ bits and starts a new conversion or calibration.

Table 28. Bit Descriptions for ADCMODE

Bits	Bit Name	Settings	Description	Reset	Access
15	REF_EN		This bit enables the internal reference and outputs a buffered 2.5 V to the REFOUT pin.	0x0	RW
		0	Disabled		
		1	Enabled		
14	HIDE_DELAY		If a programmable delay is set using the DELAY bits, this bit allows the delay to be hidden by absorbing the delay into the conversion time for selected data rates with the sinc5 + sinc1 filter. See the Delay section for more information.	0x0	RW
		0	Enabled		
		1	Disabled		
13	SING_CYC		This bit can be used when only a single channel is active to set the ADC to only output at the settled filter data rate.	0x0	RW
		0	Disabled		
		1	Enabled		
[12:11]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
[10:8]	DELAY		These bits allow a programmable delay to be added after a channel switch to allow settling of external circuitry before the ADC starts processing the input.	0x0	RW
		000	0 µs		
		001	32 µs		
		010	128 µs		
		011	320 µs		
		100	800 µs		
		101	1.6 ms		
		110	4 ms		
		111	8 ms		
7	RESERVED		This bit is reserved; set this bit to 0.	0x0	R
[6:4]	MODE		These bits control the operating mode of the ADC. See the Operating Modes section for more information.	0x0	RW
		000	Continuous conversion mode		
		001	Single conversion mode		
		010	Standby mode		
		011	Power-down mode		
		100	Internal offset calibration		
		110	System offset calibration		
		111	System gain calibration		
[3:2]	CLOCKSEL		This bit selects the ADC clock source. Selecting internal oscillator also enables the internal oscillator.	0x0	RW
		00	Internal oscillator		
		01	Internal oscillator output on the XTAL2/CLKIO pin		
		10	External clock input on the XTAL2/CLKIO pin		
		11	External crystal on the XTAL1 and XTAL2/CLKIO pins		
[1:0]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R

INTERFACE MODE REGISTER

Address: 0x02, Reset: 0x0000, Name: IFMODE

The interface mode register configures various serial interface options.

Table 29. Bit Descriptions for IFMODE

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
12	ALT_SYNC		This bit enables a different behavior of the $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ pin to allow the use of $\overline{\text{SYNC}}$/$\overline{\text{ERROR}}$ as a control for conversions when cycling channels (see the description of the SYNC_EN bit in the GPIO Configuration Register section for details).	0x0	RW
		0	Disabled		
		1	Enabled		
11	IOSTRENGTH		This bit controls the drive strength of the DOUT/$\overline{\text{RDY}}$ pin. Set this bit when reading from the serial interface at high speed with a low IOVDD supply and moderate capacitance.	0x0	RW
		0	Disabled (default)		
		1	Enabled		
[10:9]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
8	DOUT_RESET		See the DOUT_RESET section for more information.	0x0	RW
		0	Disabled		
		1	Enabled		
7	CONTREAD		This bit enables a continuous read of the ADC data register. The ADC must be configured in continuous conversion mode to use continuous read. For more details, see the Operating Modes section.	0x0	RW
		0	Disabled		
		1	Enabled		
6	DATA_STAT		This enables the status register to be appended to the data register when read so that the channel and status information are transmitted with the data. This is the only way to ensure that the channel bits read from the status register correspond to the data in the data register.	0x0	RW
		0	Disabled		
		1	Enabled		
5	REG_CHECK		This bit enables a register integrity checker, which can monitor any change in the value of the user registers. To use this feature, configure all other registers as desired, with this bit cleared. Then write to this register to set the REG_CHECK bit to 1. If the contents of any of the registers change, the REG_ERROR bit is set in the status register. To clear the error, set the REG_CHECK bit to 0. Neither the interface mode register nor the ADC data or status registers are included in the registers that are checked. If a register must have a new value written, this bit must first be cleared; otherwise, an error is flagged when the new register contents are written.	0x0	RW
		0	Disabled		
		1	Enabled		
4	RESERVED		This bit is reserved; set this bit to 0.	0x0	R
[3:2]	CRC_EN		These bits enable CRC protection of register reads/writes. CRC increases the number of bytes in a serial interface transfer by one. See the CRC Calculation section for more details.	0x00	RW
		00	Disabled		
		01	XOR checksum enabled for register read transactions; register writes still use CRC with these bits set		
		10	CRC checksum enabled for read and write transactions		
1	RESERVED		This bit is reserved; set this bit to 0.	0x0	R

Bits	Bit Name	Settings	Description	Reset	Access
0	WL16		This bit changes the ADC data register to 16 bits. The ADC is not reset by a write to the interface mode register; therefore, the ADC result is not rounded to the correct word length immediately after writing to this bit. The first new ADC result is correct.	0x0	RW
		0	24-bit data		
		1	16-bit data		

REGISTER CHECK

Address: 0x03, Reset: 0x000000, Name: REGCHECK

The register check register is a 24-bit checksum calculated by exclusively OR'ing the contents of the user registers. The REG_CHECK bit in the interface mode register must be set for this register to operate; otherwise, the register reads 0.

Table 30. Bit Descriptions for REGCHECK

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	REGISTER_CHECK		This register contains the 24-bit checksum of user registers when the REG_CHECK bit is set in the interface mode register.	0x000000	R

DATA REGISTER

Address: 0x04, Reset: 0x000000, Name: DATA

The data register contains the ADC conversion result. The encoding is offset binary, or it can be changed to unipolar by the BI_UNIPOLARx bit in the setup configuration registers. Reading the data register brings the $\overline{\text{RDY}}$ bit and the $\overline{\text{RDY}}$ output high if they are low. The ADC result can be read multiple times; however, because the $\overline{\text{RDY}}$ output has been brought high, it is not possible to know if another ADC result is imminent. After the command to read the ADC register is received, the ADC does not write a new result into the data register.

Table 31. Bit Descriptions for DATA

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	DATA		This register contains the ADC conversion result. If the DATA_STAT bit is set in the interface mode register, the status register is appended to this register when read, making this a 32-bit register. If the WL16 bit is set in the interface mode register, this register is reduced to 16 bits.	0x000000	R

GPIO CONFIGURATION REGISTER

Address: 0x06, Reset: 0x0800, Name: GPIOCON

The GPIO configuration register controls the general-purpose input/output pins of the ADC.

Table 32. Bit Descriptions for GPIOCON

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
12	MUX_IO		This bit allows the ADC to control an external multiplexer, using GPIO0/GPIO1 in sync with the internal channel sequencing. The analog input pins used for a channel can still be selected on a per channel basis. Therefore, it is possible to have a 4-channel multiplexer in front of AIN0/AIN1 and another in front of AIN2/AIN3, giving a total of eight differential channels with the AD7172-2. However, only four channels at a time can be automatically sequenced. A delay can be inserted after switching an external multiplexer (see the delay bits in the ADC Mode Register section).	0x0	RW
11	SYNC_EN		This bit enables the SYNC/ERROR pin as a sync input. When the pin is low, this bit holds the ADC and filter in reset until the SYNC/ERROR pin goes high. An alternative operation of the SYNC/ERROR pin is available when the ALT_SYNC bit in the interface mode register is set. This mode only works when multiple channels are enabled. In this case, a low on the SYNC/ERROR pin does not immediately reset the filter/modulator. Instead, if the SYNC/ERROR pin is low when the channel is due to be switched, the modulator and filter are prevented from starting a new conversion. Bringing SYNC/ERROR high begins the next conversion. This alternative sync mode allows SYNC/ERROR to be used while cycling through channels.	0x1	RW
		0	Disabled.		
		1	Enabled.		
[10:9]	ERR_EN		These bits enable the SYNC/ERROR pin as an error input/output.	0x0	RW
		00	Disabled.		
		01	SYNC/ERROR is an error input. The (inverted) readback state is OR'ed with other error sources and is available in the ADC_ERROR bit in the status register. The SYNC/ERROR pin state can also be read from the ERR_DAT bit in this register.		
		10	SYNC/ERROR is an open-drain error output. The status register error bits are OR'ed, inverted, and mapped to the SYNC/ERROR pin. The SYNC/ERROR pins of multiple devices can be wired together to a common pull-up resistor so that an error on any device can be observed.		
		11	SYNC/ERROR is a general-purpose output. The status of the pin is controlled by the ERR_DAT bit in this register. This output is referenced between IOVDD and DGND, as opposed to the AVDD1 and AVSS levels used by the general-purpose input/output pins. The SYNC/ERROR pin has an active pull-up in this case.		
8	ERR_DAT		This bit determines the logic level at the SYNC/ERROR pin if the pin is enabled as a general-purpose output. This bit reflects the readback status of the pin if the pin is enabled as an input.	0x0	RW
[7:6]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
5	IP_EN1		This bit turns GPIO1 into an input. Inputs are referenced to AVDD1 or AVSS.	0x0	RW
		0	Disabled.		
		1	Enabled.		
4	IP_EN0		This bit turns GPIO0 into an input. Inputs are referenced to AVDD1 or AVSS.	0x0	RW
		0	Disabled.		
		1	Enabled.		
3	OP_EN1		This bit turns GPIO1 into an output. Outputs are referenced between AVDD1 and AVSS.	0x0	RW
		0	Disabled.		
		1	Enabled.		
2	OP_EN0		This bit turns GPIO0 into an output. Outputs are referenced between AVDD1 and AVSS.	0x0	RW
		0	Disabled.		
		1	Enabled.		
1	GP_DATA1		This bit is the readback or write data for GPIO1.	0x0	RW
0	GP_DATA0		This bit is the readback or write data for GPIO0.	0x0	RW

ID REGISTER

Address: 0x07, Reset: 0x00DX, Name: ID

The ID register returns a 16-bit ID. For the AD7172-2, this ID is 0x00DX.

Table 33. Bit Descriptions for ID

Bits	Bit Name	Settings	Description	Reset	Access
[15:0]	ID		The ID register returns a 16-bit ID code that is specific to the ADC.	0x00DX	R
		0x00DX	AD7172-2		

CHANNEL REGISTER 0

Address: 0x10, Reset: 0x8001, Name: CH0

The channel registers are 16-bit registers that select which channels are currently active, which inputs are selected for each channel, and which setup configures the ADC for that channel.

Table 34. Bit Descriptions for CH0

Bits	Bit Name	Settings	Description	Reset	Access
15	CH_EN0		This bit enables Channel 0. If more than one channel is enabled, the ADC automatically sequences between them.	0x1	RW
		0	Disabled		
		1	Enabled (default)		
14	RESERVED		This bit is reserved; set this bit to 0.	0x0	R
[13:12]	SETUP_SEL0		These bits identify which of the four setups configure the ADC for this channel. A setup comprises a set of four registers: setup configuration register, filter configuration register, offset register, and gain register. All channels can use the same setup, in which case the same 2-bit value must be written to these bits on all active channels, or up to four channels can be configured differently.	0x0	RW
		00	Setup 0		
		01	Setup 1		
		10	Setup 2		
		11	Setup 3		
[11:10]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
[9:5]	AINPOS0		These bits select which input is connected to the positive input of the ADC for this channel.	0x0	RW
		00000	AIN0 (default)		
		00001	AIN1		
		00010	AIN2		
		00011	AIN3		
		00100	AIN4		
		10001	Temperature sensor+		
		10010	Temperature sensor−		
		10011	((AVDD1 − AVSS)/5)+ (analog input buffers must be enabled)		
		10100	((AVDD1 − AVSS)/5)− (analog input buffers must be enabled)		
		10101	REF+		
		10110	REF−		

Bits	Bit Name	Settings	Description	Reset	Access
[4:0]	AINNEG0		These bits select which input is connected to the negative input of the ADC for this channel.	0x1	RW
		00000	AIN0		
		00001	AIN1 (default)		
		00010	AIN2		
		00011	AIN3		
		00100	AIN4		
		10001	Temperature sensor+		
		10010	Temperature sensor−		
		10011	((AVDD1 − AVSS)/5)+		
		10100	((AVDD1 − AVSS)/5)−		
		10101	REF+		
		10110	REF−		

CHANNEL REGISTER 1 TO CHANNEL REGISTER 3

Address: 0x11, 0x12, 0x13, Reset: 0x0001, Name: CH1 to CH3

The remaining three channel registers share the same layout as Channel Register 0.

Table 35. CH1 to CH3 Register Map

Reg.	Name	Bits	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Reset	RW
0x11	CH1	[15:8]	CH_EN1	RESERVED	SETUP_SEL1		RESERVED		AINPOS1[4:3]		0x0001	RW
		[7:0]	AINPOS1[2:0]			AINNEG1

		[7:0]	AINPOS2[2:0]			AINNEG2						
0x13	CH3	[15:8]	CH_EN3	RESERVED	SETUP_SEL3		RESERVED		AINPOS3[4:3]		0x0001	RW
		[7:0]	AINPOS3[2:0]			AINNEG3						

SETUP CONFIGURATION REGISTER 0

Address: 0x20, Reset: 0x1000, Name: SETUPCON0

The setup configuration registers are 16-bit registers that configure the reference selection, input buffers, and output coding of the ADC.

Table 36. Bit Descriptions for SETUPCON0

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
12	BI_UNIPOLAR0		This bit sets the output coding of the ADC for Setup 0.	0x1	RW
		0	Unipolar coded output		
		1	Bipolar coded output (offset binary)		
11	REFBUF0+		This bit enables or disables the REF+ input buffer.	0x0	RW
		0	REF+ buffer disabled		
		1	REF+ buffer enabled		
10	REFBUF0−		This bit enables or disables the REF− input buffer.	0x0	RW
		0	REF− buffer disabled		
		1	REF− buffer enabled		
9	AINBUF0+		This bit enables or disables the AIN+ input buffer.	0x0	RW
		0	AIN+ buffer disabled		
		1	AIN+ buffer enabled		
8	AINBUF0−		This bit enables or disables the AIN− input buffer.	0x0	RW
		0	AIN− buffer disabled		
		1	AIN− buffer enabled		
7	BURNOUT_EN0		This bit enables a 10 µA current source on the positive analog input selected and a 10 µA current sink on the negative analog input selected. The burnout currents are useful in diagnosis of an open wire, whereby the ADC result goes to full scale. Enabling the burnout currents during measurement results in an offset voltage on the ADC. The best strategy for diagnosing an open wire is turning on the burnout currents at intervals, before or after precision measurements.	0x00	R
6	RESERVED		These bits are reserved; set these bits to 0.	0x00	R
[5:4]	REF_SEL0		These bits allow you to select the reference source for ADC conversion on Setup 0.	0x0	RW
		00	External reference.		
		10	Internal 2.5 V reference. The REF_EN bit must also be enabled in the ADC mode register.		
		11	AVDD1 − AVSS. This can be used to as a diagnostic to validate other reference values.		
[3:0]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R

SETUP CONFIGURATION REGISTER 1 TO SETUP CONFIGURATION REGISTER 3

Address: 0x21, 0x22, 0x23, Reset: 0x1000, Name: SETUPCON1 to SETUPCON3

The remaining three setup configuration registers share the same layout as Setup Configuration Register 0.

Table 37. SETUPCON1 to SETUPCON3 Register Map

Reg.	Name	Bits	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Reset	RW

		[7:0]	BURNOUT_EN3	RESERVED	REF_SEL3		RESERVED					

FILTER CONFIGURATION REGISTER 0

Address: 0x28, Reset: 0x0500, Name: FILTCON0

The filter configuration registers are 16-bit registers that configure the ADC data rate and filter options. Writing to any of these registers resets any active ADC conversion and restarts converting at the first channel in the sequence.

Table 38. Bit Descriptions for FILTCON0

Bits	Bit Name	Settings	Description	Reset	Access
15	SINC3_MAP0		If this bit is set, the mapping of the filter register changes to directly program the decimation rate of the sinc3 filter for Setup 0. All other options are eliminated. This allows fine tuning of the output data rate and filter notch for rejection of specific frequencies. The data rate when on a single channel equals $f_{MOD}/(32 \times FILTCON0[14:0])$.	0x0	RW
[14:12]	RESERVED		These bits are reserved; set these bits to 0.	0x0	R
11	ENHFILTEN0		This bit enables various postfilters for enhanced 50 Hz and 60 Hz rejection for Setup 0. The ORDER0 bits must be set to 00 to select the sinc5 + sinc1 filter for this bit to work.	0x0	RW
		0	Disabled		
		1	Enabled		
[10:8]	ENHFILT0		These bits select between various postfilters for enhanced 50 Hz and 60 Hz rejection for Setup 0.	0x5	RW
		010	27 SPS, 47 dB rejection, 36.7 ms settling		
		011	21.25 SPS, 62 dB rejection, 40 ms settling		
		101	20 SPS, 86 dB rejection, 50 ms settling		
		110	16.67 SPS, 92 dB rejection, 60 ms settling		
7	RESERVED		This bit is reserved; set this bit to 0.	0x0	R
[6:5]	ORDER0		These bits control the order of the digital filter that processes the modulator data for Setup 0.	0x0	RW
		00	Sinc5 + sinc1 (default)		
		11	Sinc3		
[4:0]	ODR0		These bits control the output data rate of the ADC and, therefore, the settling time and noise for Setup 0. Rates shown are for the sinc5 + sinc1 filter. See Table 20 to Table 23.	0x0	RW
		00000	31,250		
		00001	31,250		
		00010	31,250		
		00011	31,250

		[7:0]	RESERVED	ORDER3		ODR3						

OFFSET REGISTER 0

Address: 0x30, Reset: 0x800000, Name: OFFSET0

The offset (zero-scale) registers are 24-bit registers that compensate for any offset error in the ADC or in the system.

Table 40. Bit Descriptions for OFFSET0

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	OFFSET0		Offset calibration coefficient for Setup 0.	0x800000	RW

OFFSET REGISTER 1 TO OFFSET REGISTER 3

Address: 0x31, 0x 32, 0x33, Reset: 0x800000, Name: OFFSET1 to OFFSET3

The remaining three offset registers share the same layout as Offset Register 0.

Table 41. OFFSET1 to OFFSET3 Register Map

Reg.	Name	Bits		Reset	RW
0x31	OFFSET1	[23:0]	OFFSET1[23:0]	0x800000	RW
0x32	OFFSET2	[23:0]	OFFSET2[23:0]	0x800000	RW
0x33	OFFSET3	[23:0]	OFFSET3[23:0]	0x800000	RW

GAIN REGISTER 0

Address: 0x38, Reset: 0x5XXXX0, Name: GAIN0

The gain (full-scale) registers are 24-bit registers that compensate for any gain error in the ADC or in the system.

Table 42. Bit Descriptions for GAIN0

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	GAIN0		Gain calibration coefficient for Setup 0.	0x5XXXX0	RW

GAIN REGISTER 1 TO GAIN REGISTER 3

Address: 0x39, 0x3A, 0x3B, Reset: 0x5XXXX0, Name: GAIN1 to GAIN3

The remaining three gain registers share the same layout as Gain Register 0.

Table 43. GAIN1 to GAIN3 Register Map

Reg.	Name	Bits		Reset	RW
0x39	GAIN1	[23:0]	GAIN1[23:0]	0x5XXXX0	RW
0x3A	GAIN2	[23:0]	GAIN2[23:0]	0x5XXXX0	RW
0x3B	GAIN3	[23:0]	GAIN3[23:0]	0x5XXXX0	RW

(RU-24)
Dimensions shown in millimeters

ORDERING GUIDE

Models[1]	Temperature Range	Package Description	Package Option
AD7172-2BRUZ	−40°C to +105°C	24-Lead Thin Shrink Small Outline Package [TSSOP]	RU-24
AD7172-2BRUZ-RL	−40°C to +105°C	24-Lead Thin Shrink Small Outline Package [TSSOP]	RU-24
AD7172-2BRUZ-RL7	−40°C to +105°C	24-Lead Thin Shrink Small Outline Package [TSSOP]	RU-24
